

Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

- + *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
- + *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
- + *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
- + *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter <http://books.google.com> durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

GLYCOSURIA AND INSANITY (a)

By W. R. DAWSON, M.D. (DUBL.),
F.R.C.P.I.,

Medical Superintendent, Farnham House, Finglas; Examiner in Mental Diseases, University of Dublin.

NOWADAYS, when it is freely asserted that many, if not most, forms of mental disease are due to toxic influences, sometimes rather remote, the study of states undoubtedly toxic, in their relation to morbid psychical phenomena, has acquired an added interest. To such states belong certain cases of glycosuria associated with insanity, of which an unusual proportion, some seven in all, have come under my observation during the past fifteen months, and these I propose to discuss briefly here.

Disregarding minute distinctions, such cases may be said to come under one of two heads, viz., those in which morbid mental phenomena have arisen in the course of glycosuria, which presumably gave rise to them, and those in which glycosuria developed as a symptom during an attack of mental disease, the former class being rare, the latter fairly common. It is not, indeed, unusual to meet with some mental depression and irritability of temper in persons suffering from diabetes, but in few do these phenomena advance to actual insanity. That they do so sometimes, however, has long been recognised, the typical form of psychosis being a mental depression which, as Maudsley (b) says, "is inclined to be of a whining and wailing character, tedious and chronic, largely hypochondriacal in its complexion." Of this uncommon "diabetic insanity" the following case seems to be an example:—

CASE I.—Married woman, *æt.* 43, admitted October 15th, 1900, suffering from simple melancholia. There was some neuropathic heredity. Though not robust, she had had no serious illnesses, but at the birth of her youngest child, about 3½ years before, there had been severe hæmorrhage, from the results of which she suffered for a long time. Menstruation was always normal, and she had three children, all living. For about twenty years, however, there had been an excessive flow of urine, worse at times, and of late a sweet smell had been observed from it; but her doctor was not informed, and no urinary examination was made. In her younger days she was of a cheerful disposition, but about eighteen years back she had had an attack of mental depression, and ever since similar seizures about twice a year, which, however, have been increasing of late in severity, duration and frequency. On two previous occasions the attacks were very severe (*i.e.*, after her marriage, and from fatigue and anxiety in nursing a sick relative), but she had never been in an asylum. The character of the attacks was always the same, viz.,

simple melancholia, accompanied by failure of memory, somnolence, dulness of the special senses, and constipation. During her pregnancies and for about three months subsequently she was always mentally well.

In the spring of 1900, during one of her ordinary periods of depression, she undertook some work in connection with the death of a relative, and though better while it lasted she afterwards somewhat suddenly became depressed and physically weak. Change of scene failed to bring mental improvement, though physically she became unusually strong and well for her, still, however, suffering from constipation and some insomnia. As she was restless and miserable, spoke of suicide, and once struck a relative in a fit of excitement, she was seen by Dr. Revington, who advised her removal to an asylum.

She was a tall, spare, pale woman, with a neurotic type of face, and looking fully her age. Mentally, it soon became apparent that she suffered from a weak and fretful depression, persistent but not very acute, and shown by restlessness and querulousness, constant questions in a whining tone as to whether "nothing could be done to make her more contented," and complaints of failure of attention, loss of interest in life, and of affection for her relatives, and the like. Her sleep was poor. Temperature subnormal. The pupils were found to react normally, and it may be said that the fundus oculi, when examined at a later date, showed no morbid appearances. The acuteness of the senses (except perhaps touch) was impaired. Both knee-reflexes were exaggerated. The heart was healthy, but blood-pressure was high (130 mm.). The lungs seemed healthy also, though there was some relative dulness of the right apex. The bowels tended to be constipated, but the appetite was large, and there was no special thirst. Micturition was frequent, and the urine on the day after admission was pale, *sp. gr.* 1018, and contained sugar. During the earlier part of her residence a sweetish smell was sometimes noticed from her breath. Treatment was at first merely tonic and directed to the relief of symptoms, especially constipation and insomnia, the latter of which yielded to moderate doses of equal parts of sulphonal and trional, which were given nightly, the dose being gradually lessened until after six or seven weeks it could be dispensed with altogether. At first an attempt was made to influence the mental state through the blood-pressure, by giving erythrol tetranitrate, but without success. Nevertheless, some slight improvement soon began to be perceptible, and in ten days she was looking better and had gained a little in weight. On November 25th the urine, which measured 40 ozs. for the twenty-four hours, contained a trifle over ½ oz. of sugar, and on the 30th she was put on anti-diabetic diet, though carbohydrate food was not entirely stopped. Micturition had previously become less frequent, and mental improvement speedily manifested itself, the patient becoming less depressed, and losing her whining ways. On November 8th the quantity of urine had fallen to 26 ozs., and on the 9th it was 30 ozs., the amount of sugar present on the latter date being only .09 oz. Six days later the patient rather suddenly brightened up and became cheerful and contented, and from this time (with the ex-

(a) Read before the Medical Section, Royal Academy of Medicine, Ireland, Dec. 15th, 1901.

(b) "Pathology of Mind," 1895, p. 118.

ception to be presently noted) she continued so, showing indeed, perhaps, a little reactionary elation. Her physical health was also good, but she lost weight considerably during the first fortnight under antidiabetic diet, after which she slowly regained it. On November 27th the twenty-four hours' urine measured 31 ozs., and contained an infinitesimal amount of sugar, which had completely disappeared by December 5th, though the quantity of urine had increased to 50 ozs. On December 6th the diet was somewhat relaxed, but four days later the extra carbohydrate was reduced again, as there was a slight return of the feeling of weariness and also of the quernulousness, while at the same time a good deal of sugar reappeared in the urine. The mental change was noted, however, before the diet was altered. By December 11th the patient was better again, while the amount of sugar had diminished to a mere trace, the quantity of urine being 33 ozs., and on the 13th, the morning urine was found to contain no sugar, while after breakfast there was a trace, and at 5.30 p.m. a little more, the specific gravity rising from 1011 to 1026. On the 18th the urine measured 52 ozs., and was free from any appreciable amount of sugar, and the patient was physically well, and mentally bright and cheerful. Blood pressure had fallen to 90 mm.. It should be said, however, that some enlargement of the liver was detected on this day, but this had not previously been looked for. On this date she was discharged. During her residence menstruation was regular and normal. Since leaving she has persisted with the special diet, and I have recently been informed that she has steadily improved, and has gained in weight, while the urine, whenever examined, has been free from sugar. On three occasions there were signs of slight depression, but notwithstanding this her own opinion is that she has not been so well for twenty years.

We have here, therefore, a history of polyuria and recurrent melancholia running contemporaneously over many years, with general debility, the melancholia being of the type characteristic of diabetic insanity. In a severer mental attack sugar is found, and with the disappearance of the sugar under treatment the mental symptoms recover, returning slightly with recurrence of the glycosuria, to disappear again as it diminished. Lastly, persistence in the treatment has produced a continuance of physical and mental health such as the patient had not enjoyed for a long time, and this has lasted for nearly a year. It therefore seems probable that this is a case of very chronic diabetes giving rise to mental symptoms, although it must be admitted that some of the phenomena are unusual, such as the long duration (especially as the disease began in youth) and the absence of sterility; while the non-examination of the urine previous to admission unfortunately precludes absolute certainty. Interesting points in the later attack are the small quantity of urine passed, and the blunting of the special senses, especially that of taste.

The remaining cases may be more briefly dealt with, as they all probably belong to the second class, that in which the glycosuria is merely a symptom of the insanity, or rather of the disorder of the nervous system underlying it. In the first two cases, however, there appeared to be a definite relation between the glycosuria and the mental symptoms.

CASE II.—The first is that of a man, *æt.* 34, without known neuropathic heredity, who was admitted last May, with the following history. He had an attack of mental depression seven years before, since when he had worried a good deal about a scarcely noticeable facial deformity, imagining that people observed it and blamed him for causing it. A second attack of depression had followed influenza, and the present one developed after what appears to have been influenza also, about two months before admission. He manifested marked suicidal tendencies, which were the cause of his removal to an asylum, and the mental pain was acute at times, but his mind could be diverted from it by cheerful surroundings. His bodily health was good,

and the organs sound. The pulse was 56, the blood-pressure high, tongue furred, bowels constipated. The knee reflexes were increased. The urine was pale, of high specific gravity, and contained sugar, and he said that sometimes the quantity was large. Thirst was not complained of. The diagnosis was an attack of acute melancholia grafted on a mildly delusional state of mind, and the treatment was tonic with attention to the bowels and sleep, substitution of saxon for sugar in his diet, and as much amusement and occupation as possible. The sugar disappeared from the urine in about a month, the depression coincidentally dwindling. A fortnight later he was discharged, the melancholia being practically gone, though he still worried a little about his fancied deformity. Blood-pressure was normal. After leaving he went for a prolonged change to various places of resort, continuing to improve (though he soon dropped the treatment), and I heard three or four days ago that he was doing his work, and was in excellent health. The urine when examined a few weeks after his discharge contained no sugar.

I am inclined to think that in this case both the mental symptoms and glycosuria were the result of the influenza, but that the latter may have had a prejudicial effect in increasing and keeping up the former.

CASE III.—The next case was that of a man of 77, of splendid physique, and very sound for his age. Fourteen years before he had received a blow from a block on the back of his head, and six months later was seized with an attack of mental depression accompanied by religious delusions, from which he recovered in about two months, remaining well mentally since. General health was good, but he had suffered from phlegmon of the leg about five years before, and the veins of both legs were thrombosed. He had been unusually quiet during the winter, but in the middle of February was suddenly seized with depression, accompanied as before by religious delusions. He was admitted about a month later, and was then acutely melancholic and delusional. Physically there was little abnormal, but the urine was of high specific gravity, and contained a trace of sugar. Blood-pressure high, pulse 84. The treatment, as before, was mainly general, but after a time sugar was withdrawn from the diet. After a few days he began to improve mentally, and he was discharged practically recovered in about six weeks, the sugar being then reduced to the least possible trace. He has since remained well.

It is just possible that in these cases the glycosuria may have preceded the mental symptoms, being caused in the former by toxic influence, in the latter by some slight injury to the cerebellum or medulla; but the data are quite insufficient to lend any colour to this theory, and the previous physical health of the patients is against it.

The remaining cases, four in number, only gave evidence of glycosuria on isolated occasions, and there is, therefore, no difficulty in classifying them. They are as follows:—

CASE IV.—A case of paranoia, with delusions of suspicion and persecution, in a man, *æt.* 32, who is morose, ill-tempered, and generally depressed. Albumen was found in the urine several times, but sugar on two occasions only—on May 27th and 30th last, at a time when his delusions were unusually rampant. He had also a prejudice against meat at this period, and was, therefore, living largely on carbohydrates. He always takes a good deal of fluid.

CASE V.—A case of subacute mania of nine months' standing in a girl of 27, with a tendency to stupor. Her urine reduced Fehling's solution on one occasion shortly after admission (in Dec., 1900), and there was a trace of sugar again ten days later. Slight traces of sugar were again detected in April and May, by which latter month the patient had practically recovered, but it had disappeared again before her discharge. The quantity, though always minute, increased somewhat after thyroid treatment, possibly owing to the milk diet given. [The treatment itself, however, may have been partly or

wholly responsible.] She has remained well since leaving, and gained in weight.

CASE VI.—An attack of acute mania, with stupor, and delusions of an unpleasant type, in a female paranoiac of 33. A trace of albumen and some sugar were present on June 5th last. On the 8th the total quantity of urine was only 14½ ozs., sp.gr. 1030, and it contained albumen and a trace of sugar (4½ gr. in all). The sugar had practically disappeared by June 13th, and was not again found. Blood-pressure was high, but fell with improvement, and she made a good recovery from the acute seizure in about four months.

CASE VII.—The last case was one of acute confusional insanity of about two and a-half months' duration in a girl, aged 29, admitted November 1st. There was a trace of sugar on admission, and also of albumen, while on November 4th, when the quantity of urine was 24 ozs., sp.gr. 1022, the albumen had disappeared, but there was still a trace of sugar. On December 1st sugar had disappeared, and the urine was otherwise normal except in quantity, which was 80 ozs. There has been no return of the glycosuria, but the patient is still passing a large quantity of urine (81 ozs. on the 11th). Blood-pressure was high at first, but has fallen considerably, and the patient is otherwise progressing favourably.

Taking all the cases together, it will be seen that their predominant characteristic was mental discomfort in varying degree and kind, except perhaps in one case (the fifth) where the glycosuria was so slight as to be negligible; and correspondingly the blood-pressure was high whenever taken during the acute stage. This association of glycosuria with melancholia was found by Dr. Leeper (a) also in three cases which were published by him recently, and corresponds with the more extended observations of Emil Raimann (b) and others, so that the connection must be essential. In cases of true diabetic insanity the form of the melancholia is that characteristic of cerebral anaemia, and if this be taken in conjunction with the atrophic character of the secondary morbid changes found in diabetic brains, it becomes clear that the mental symptoms are due to cerebral malnutrition, in whatever way this may be caused. It follows also from this that persistent glycosuria, or rather glycaemia, even if it be of secondary origin, is not unlikely to act injuriously on the nervous centres. As to the origin of the sugar in this second class of cases, it is highly probable that Raimann is right in considering it of alimentary origin, and due to a deficiency in the capacity of assimilating sugar (a deficiency which he has found to exist in the highest degree in melancholia, though also present in acute confusion and some other forms of insanity) and which is merely a part of the general disorder of metabolism in the insane.

In conclusion, it may be pointed out that glycosuria is not necessarily a symptom of bad prognostic import in insanity, as five out of my seven cases made good recoveries, and one more is in a fair way to do so, while the remaining case is for other reasons hopeless.

HEMICHOREA AND PAROTITIS COMPLICATING A CASE OF DIABETES. (c)

By GEORGE PEACOCKE, M.D., F.R.C.P.I.,
Assistant Physician, Adelaide Hospital, Dublin.

ON April 29th of the present year a man, æt. 64, was admitted to the Adelaide Hospital under my care. He stated that his present illness began about two months previously with loss of appetite, great thirst, and increased flow of urine. He had also lost

about five stone in weight during this period. Diabetes was suspected as the cause of his trouble, and an examination of the urine confirmed the diagnosis. Quantitative analysis of the urine by Fehling's solution showed on May 2nd 2·7 ozs. of sugar per diem, the amount of urine passed being 89 ozs. A subsequent analysis gave 9 ozs. of sugar per diem, the amount of urine passed being 100 ozs.

From the outset he seemed an unfavourable case, drowsiness, at times almost approaching coma, was a marked symptom throughout his illness, and he died on May 28th, just four weeks after admission to hospital.

On May 4th it was noticed that his left arm and leg were in almost constant movement. These movements were choreiform in character, irregular and purposeless. Their severity altered at different times—emotion always made them worse. So severe did they become that it was practically impossible without constant watching to keep the clothes on his bed and an acute eczema of the legs resulted, mainly, I think, from the constant friction of one limb against the other. By a strong effort of will he was able to control these movements for a few minutes, but they soon returned again. They ceased during sleep. I first tried chloral, bromide of potassium and tincture of hyoscyamus without any effect, then hypodermics of hyoscyne with a similar result.

On May 8th I gave 10 minim doses of liq. arsenicalis every eighth hour, and that night he had 20 grs. of trional, partly to procure sleep and also in the hope that it would have a directly beneficial effect on the chorea.

The following day there was a decided improvement in his condition, the arsenic was continued and he was given trional every night. The movements ceased entirely on the 13th May. Whether this result was due to the arsenic or to the trional is open to question. The value of arsenic in the treatment of chorea is well known. Trional has, as yet, been seldom employed.

In the *British Medical Journal* of November 2nd, 1901, Dr. Meade records a case of acute chorea in a lady, æt. 25, who was six months pregnant. Her symptoms, which were severe, had resisted treatment by arsenic and bromides. When trional was given 25 grs. at night and 15 grs. the following morning improvement rapidly followed, and by June 1st, or ten days after the first administration of the drug, her condition was so much better that only 12 grs. was given at bedtime, and this was discontinued a week later.

Last January a girl, æt. 11, was admitted to the Adelaide Hospital under the care of one of my colleagues. She was suffering from acute chorea, and the ordinary sedative drugs were tried without success. I advised the use of trional in 3 gr. doses every fourth hour. Improvement rapidly followed, and the drug was discontinued a fortnight later, all the choreic symptoms having subsided.

In the "Medical Annual" for 1900, Dr. Adams has a short note on the use of sulphonal and trional in chorea. He considers the latter drug more preferable, and is also of opinion that it is more useful than the drugs of a sedative nature that are usually employed. I have as yet had few opportunities of testing the value of trional in the treatment of chorea. My experience so far will, however, lead me to give it a further trial when a suitable case comes under my care.

The occurrence of chorea in a man over sixty is a rare event. The types of chorea known as Huntington's chorea and senile chorea, which occur in patients passed middle life, are chiefly characterised by their chronicity, the former being incurable and showing a strong hereditary tendency

(a) *Journ. of Ment. Science*, October, 1901, p. 758.

Recovery from the latter occasionally occurring after months or years, treatment having apparently little or no effect on the result. The present case is evidently not an example of either of these forms; can we regard it as pathologically related to Sydenham's chorea? Little that is certain is at present known of the pathology of this affection. The embolic theory so long held, especially by English writers, is now rightly discarded, as there is no evidence pathologically to support it. Many consider that it is merely a functional brain disorder, an instability of the nerve cells, and instance in proof of this those cases which occur as the immediate result of some sudden fright or violent emotion.

Whilst others account for the symptoms by the action of some toxic agent, the result either of an altered blood state or of some infective organism introduced into the system from without. In favour of this view it has been urged that both rheumatism and endocarditis, which so commonly occur in association with chorea, have their origin in a common cause—some infectious agent, that cases are frequently met with in the course of the infectious fevers, notably scarlet fever (according to Ross), in puerperal fever, and also after gonorrhœa.

Denne records a remarkable case which appeared after the use of iodoform in a fistula connected with caries of the cervical vertebra, the symptoms of which ceased when the iodoform was suspended and returned on resumption of the treatment. The poisons which circulate in the blood in diabetes can produce a profound effect upon the nervous system, the occurrence of coma, of peripheral neuritis, of toxic amaurosis are sufficiently striking examples. May they not also in other cases so act on the nerve cells controlling the motor apparatus as to cause symptoms, such as occurred in the present case, symptoms that were at any rate clinically identical with those of chorea.

The second complication which occurred in the present case was parotitis. On May 11th I first noticed a swelling over the parotid region on the right side. At first this seemed to give little trouble, but as it increased in size it became tender and gave rise to considerable pain. It was not until the 16th that there was any elevation of temperature, and then only a very slight one. During the last few days of the patient's life the temperature varied between 100° and 101.6° —the latter being the highest recorded. When it appeared to me that a suppurative process was going on in the gland I asked Mr. Gordon to see the case with me, but owing to the patient's general condition, and also to the fact that no part was specially presenting, no surgical interference was attempted.

I can find no mention of a similar condition occurring in the course of diabetes, nor can I offer any explanation of its cause in the present case. Apart from specific parotitis or mumps, inflammation of the parotid gland has been observed in the course of the infectious fevers, typhus, enteric, pneumonia, pyæmia, &c., and in connection with injury or disease of the abdomen or pelvis. Of 101 cases collected by Stephen Paget and mentioned by Osler, 10 followed injury or disease of the urinary tract, 18 were due to injury or disease of the alimentary canal, and 23 were due to injury or disease of the abdominal wall, the peritoneum or the pelvic cellular tissue. One gland only is usually attacked, and in 78 cases in which the termination is recorded 45 suppurated and 33 resolved without suppuration.

That in many cases the origin is septic there can be little doubt, and when occurring in the course of pyæmia the condition is usually regarded as metastatic. In others it may possibly arise from irritants which proceed from the decomposition of matters

retained in the mouth and gain access to the gland through Steno's duct, or as the result of dryness of the buccal mucous membrane leading to an obstructed state of Steno's duct with decomposition of the retained salivary secretion. "For such an opinion," says Hilton Fagge, "there seems to be no sufficient foundation." Whether the presence of diabetes had any direct influence in the production of parotitis in the present case I must leave to others more competent to form an opinion than I am; its relation to the choreic symptoms, though obscure, seems perhaps more intelligible. The occurrence of two unrecorded complications in the course of the disease is at any rate a matter of some curiosity, if not considerable interest.

NOTES OF A

CASE OF CÆSAREAN SECTION. (a)

By ANDREW J. HORNE, F.R.C.P.,

Examiner in Midwifery, Royal College of Physicians of Ireland,
Master of the National Lying-in Hospital, Dublin.

Of the many absorbing topics of medical literature of the many changes in the art of surgical treatment made in the two last decades, and of the many glorious achievements attained in this period under aseptic and antiseptic methods, to the obstetrician the surgery of the uterus, when complicated with a living fœtus at or near the full term of pregnancy, is the most interesting and important subject he may be called upon for his opinion. In drawing your attention to the subject of Cæsaean section this evening it is not my desire that any very special inference is to be drawn from the case I report, but my desire is simply to put it on record among the Transactions of the Obstetrical Section of the Royal Academy of Medicine in Ireland; secondly, my desire is that it may bring forth a discussion from the members present; and last, my desire is to thank Dr. Elizabeth Massey for the notes; also for her promptitude in bringing the case into hospital I chiefly attribute the success. Mrs. T., æt. 23. Second pregnancy. Was admitted into the National Maternity Hospital, at 11.30 a.m., on Sunday, July 21st, 1901. She was born in the North, and was considered a weakly child in her first years. She was reared in a chair, as she had not the use of her legs, until she was five years old. First labour, October, 1898, took place in the Rotunda Hospital. Patient was in labour some ten hours, when, after a prolonged instrumental delivery, a dead fœtus was extracted. Her last menstruation was on October 22nd, 1900. At 6 a.m. on Sunday, July 21st, the membranes ruptured. At 10 a.m. she was visited by Dr. Elizabeth Massey, and she diagnosed a highly contracted pelvis, and had the patient at once removed to hospital. I saw her at noon. Examination.—The patient was small, delicately built. Height, 4 ft. 4 ins. Measurement from crest of ilium to sole of foot, 29 ins.

From symphysis pubis to umbilicus $6\frac{1}{2}$ inches.

From ensiform cartilage to umbilicus ... 9 inches.

From left ant. spine to umbilicus... 9 inches.

From right ant. spine to umbilicus ... 9 inches.

From ant. sup. spine to other in front ... 12½ inches.

Around pelvis at head ant. spine ... 32½ inches.

From symphysis pubis 2 x 1 to middle of spine ... 13 inches.

Internal.—From promontory of sacrum to lower angle of symphysis pubis, 2½ inches.

The cervix was dilated to about the size of a florin, the head of the child could be felt above the brim. On external palpation it was movable. Back of fœtus to the left. The heart sounds were audible immediately below the level of umbilicus, and to the left about 140 beats to the minute. I at once telephoned to the

(a) Paper read and patient shown before the Royal Academy of Medicine, Ireland, December 20th, 1901. Discussion will be found under Meetings of Societies.

Rotunda, and have to thank Dr. Lloyd for having supplied me with the particulars of her previous delivery, and as the measurement of the pelvis corresponded with my own, I decided on performing Cesarean section, the mother having previously expressed the desire that her child should be born alive.

Operation.—At 3.30 p.m. patient was placed under chloroform by Dr. Massey, when ether was substituted, assisted by my colleague Dr. Barry. An abdominal incision was made, extending from three inches above umbilicus to two inches of symphysis pubis. The uterus was delivered through the abdominal wound, which was temporarily united behind it. An incision was made through the uterine wall, commencing high up at the fundus but avoiding the lower uterine segment. The placenta was in front and was rapidly cut through; bleeding was at once profuse. The child was seized by the buttocks and extracted, the head followed without any difficulty. The infant, a female, at once cried out. The assistant's hand grasped the uterine edges until I applied an elastic ligature. The placenta was detached without difficulty. The uterus contracted well, hot sterilised towels being applied, the wounded surfaces were brought together by means of six deep sutures and four superficial silk sutures. The abdomen was closed likewise, using silk for the deep sutures and silkworm gut for the superficial. The operation lasted forty minutes, the patient leaving the table in good condition. Pulse 105.

The child, a healthy girl, weighed 7 lbs. The progress of the case was most satisfactory. Pain was experienced for only some four hours after operation, which was relieved by $\frac{1}{2}$ gr. of morphia hypodermically. Thirty hours after delivery she was given 5 gra. of calomel, during that night she vomited on four occasions what was described as dark, bilious-looking matter. The bowels were moved by an enema of soap and water to which a teaspoonful of common salt was added. The further convalescence was uneventful. The mother was able to suckle her child. She sat up on the twenty-first day, and left the hospital on the thirtieth day after operation. The three important questions I had to decide on my first visit to this patient were:—First, should I allow the labour to proceed, with the object of giving nature a chance of so moulding the head, that I might eventually deliver by means of forceps or symphysiotomy; secondly, should I perform a Porro's operation; or finally, a Cesarean operation. I chose the latter for two reasons—namely, the mother was most anxious a living child should be born, and knowing the result of her previous labour, besides the most important condition that there had been no examination previous to her admission to hospital. The important points to my mind of this case, and upon which I would like to have the opinion of this Section of the Academy, are in connection with the uterine incision, whether one should adopt what is known as the classical anterior incision, or longitudinal, or the transverse incision as recommended by Fritsch. Recent authorities, notably Schroeder, are much in favour of the latter. The advantages he claims: When made on a woman in the Trendelenburg position this incision allows the waters to escape over the thorax of the patient; the peritoneum is thus exposed to far less risk of infection. Moreover, it is the best way to avoid the placenta, and finally, as the incision is parallel to the vessels of the fundus, it is not followed by more hemorrhage than the longitudinal one; in fact, among ninety-four cases of the transverse incision, Schroeder has only found fourteen in which any considerable hemorrhage at the time of the incision is recorded, and in most cases it is stated that the bleeding ceased when the uterus contracted. Again, by the incision of Fritsch a more rapid extraction of the fetus is accomplished. By it one almost invariably comes upon one end of the child, either the head or the breech, by the longitudinal incision upon the trunk. When the fetus has been removed it is perfectly easy to inspect the whole of the uterine cavity down to the lower segment. Objection has been made that the transverse incision is likely to be followed by adhesion to the intestine, but in a paper published in the

Centralblatt f. Gyn., 1899, by H. Ludwig, of Vienna, in two Cesarean operations on the same woman the uterus was opened by a transverse incision through the fundus, and the child extracted alive. The result of the first operation was blameless in so far that the adhesion to the uterine cicatrix was only evident through the old silk suture.

I shall not discuss the Cesarean operation in its relations to other operations, such as symphysiotomy, craniotomy, and the Porro's operation, as the time at my disposal is too limited, even if I had the desire. We cannot, however, shut our eyes to the fact that the Cesarean operation is gradually being restored to a position not unlike that of ovariectomy, so that we can speak with confidence, as a rule, to a favourable result. No longer shall we be confronted with the words or saying:—"Spare the mother, no matter about the child." The dangers attending the Cesarean operation ought not to be as great, certainly not greater, than an ovariectomy, but students must be more fully instructed in the recognition of degrees of pelvic obstruction, so that it will not be necessary for the obstetrician to learn through delay, or through failure with forceps version or craniotomy, that a Cesarean section is demanded. I shall not touch on eclampsia, placenta previa, prolapsed cord, &c., on the light of these forming the most recent indications for Cesarean section. In the performance of Cesarean section our motto should be: Operate early, delay is fatal.

GALL-STONE ILEUS. (a)

By H.R. KAREWSKI,
Of Berlin.

IN general the passage of the gall-stone *per vias naturales* was the most desirable. But sometimes this process caused great danger by inducing blocking of the bowel. The number of cases of ileus from this cause was not large, so that histories of the kind were desirable. Then again, the views as to treatment were decidedly antagonistic, viz., as to whether cases should be treated expectantly or by prompt operation. If Rehn removed calculi from fear of subsequent obstruction, Naunyn was inclined to wait. The group of symptoms of gall-stone ileus was very peculiar, and did not lend itself to the formation of a diagnosis. There was no simple process, no simple obstruction ileus. From numerous observations it was ascertained that the ileus was not dependent on the size of the stones, and stones of a size relatively small might, under certain circumstances, set up fatal ileus, whilst on the other hand large concretions might be passed without trouble. The cause of this difference lay by no means in a narrowing of the lumen of the bowel. Moreover, ileus only exceptionally followed the entrance of the stone into the bowel immediately, it had generally been in the intestines for some time, and the patient in many cases had never before suffered from symptoms of cholelithiasis, or had only had them years before. Under these circumstances an explanation of the course of events was difficult; and treatment was also proportionally so. A change or a temporary cessation of the symptoms was also common. Then came the question how ileus was set up, and what diagnostic factors could lead us to a recognition of it? The communication of some observations might lead to an answer to the question.

Case 1.—In December, 1899, a man, æt. 56, was admitted into hospital with violent colic and vomiting that could not be arrested by morphia, &c. Twenty hours later feculent gases were expelled by eructation; though the bowels had been open. After injection of two litres of water copious evacuation took place, whereupon the threatening symptoms subsided. Five weeks later the symptoms returned after a heavy meal, with vomiting of food, then of bile, and lastly of intestinal contents. By washing treatment and morphia subcutaneously and injection the symptoms again receded in thirty-six hours, and in April, 1899, a large gall-stone was voided per anum.

(a) Read before the Society für Innere Medizin, Berlin.

Case 2.—A lady, *æt.* 73, was attacked with vomiting and severe pain in the gastric region on January 10th, 1894. The vomit was *fecal*, no stool, nor flatus. Four days later a motion was passed, but there was still violent pain; a hardness could be felt to the right, and fever set in. A tumour the size of a child's hand could now be made out distinct from the liver. On account of the serious condition of the patient operation was decided upon; an incision made over the site of the tumour, an abscess was found, and within it a large gall-stone. Complete recovery. The patient stated that fifty years before she had suffered from spasm of the stomach. Had the stone escaped then?

Case 3.—A woman, *æt.* 37, in a poor state of health, suffered from gastric pains and vomiting. For about two years there had been intestinal stenosis, with strong peristaltic movements mostly to the left of the navel, and here some resistance could be felt. At times the patient had had foul smelling vomit and complete ileus, but she had always improved under expectant treatment. He first saw her on November 1st, 1897. Perforating gastric ulcer was first thought of, but the resistance was too deep for that, the patient had also had slight jaundice, so a diagnosis was arrived at of purulent cholelithiasis and passage of a gall-stone into the bowel. Operation was decided on, and extensive adhesions of loops of intestine were found, and on the left an old abscess cavity, at the bottom of which lay two gall-stones, each the size of a hazel nut. The intestinal stenosis was caused by kinking of intestine due to the adhesions. The patient did well.

Case 4.—A woman, *æt.* 60, had for twenty-two years suffered from attacks of pain under the left ribs with bilious vomiting; she was thought to be neurotic. Three years ago she had an attack, and underwent treatment in Wiesbaden. A year ago she had another violent attack after influenza. Improvement took place, but from that time she always vomited after food. In September last, after supper at a restaurant, she had profuse vomiting and severe colic in the left and upper abdominal region, and twelve hours later *fecal* vomiting. The abdomen was distended, and in the region of the navel was a sausage-shaped hardness. After rectal irrigation some improvement, but the *fecal* vomiting returned, and the patient became collapsed. Laparotomy was performed, and the hardness was found to be a loop of intestine filled with calculi. As the vomiting continued after removal of the stones, the stomach was washed out, when (thirty-six hours after operation) the vomiting ceased, and in another twelve flatus was passed. Then uninterrupted recovery.

Case 5 (from the practice of Hr. Wiesenthal).—A gentleman of fifty-four had suffered for years from attacks of pain under the right ribs, with icterus and vomiting. In such an attack the vomit was black; there was great meteorism, notwithstanding the passage of flatus. High oil enemata and aqueous irrigation gave no help and the patient died, and the autopsy revealed a large gall-stone above the ileo-cæcal valve.

The great variety of the symptoms that might appear were illustrated in the cases given. Only in about 5 per cent. of cases in which gall-stones were found after death did symptoms appear during life. It must not be assumed that large gall-stones could pass through the duct into the bowel; it could only be by ulceration preceded by adhesion. It was more favourable when the stone passed in this way into the colon, but even in such a case occlusion has sometimes occurred. The usual course, however, was into the duodenum. Blocking of the bowel by the stone was favoured by certain factors. First, was the unfavourable relation as to size—all intestines were not of the same size, and stones that would pass through some could not through others. The lumen also diminished in size as far as Banhini's valve, and blocking could easily take place in the lower parts. Other circumstances also favoured occlusion. A loop of intestine might be dragged down into the pelvis, and fixed by the weight of the stone, or the stone might become encapsuled, or contraction of the walls might be set up. Small stones were repeatedly the cause of disturbance. Mostly ileus was set up by inflammation. Irritation of

the bowel might set up contractions, and although by paralysis of the bowel the stone might be allowed to pass on, peritonitis might follow with its consequences. A decided diagnosis was very difficult. Diagnosis might be aided by: the advanced age of the patient, the female sex, the variation of the symptoms between ileus and a patent bowel, the high seat of the obstruction, and the unusual retention of the patient's vital powers.

As regards treatment, the usual remedies were sometimes successful, sometimes not. The attempt had been made to prove by statistics that the expectant mode of treatment was the better. But such statistics were not decisive because many of the cures among them would certainly not have been submitted to operation by the surgeon. If statistics of the last ten years were taken they would be in favour of operation. The operation was not a big ore by itself. If treatment by drugs, &c., did not give relief quickly operation should be proceeded with; this permitted of certain diagnosis and removal of the block. He therefore recommended operation when grave symptoms were present, and this should not be deferred too long.

Transactions of Societies.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, DEC. 19TH, 1901.

Dr. H. A. CALEY, Vice-President, in the Chair.

INFANTILE SCURVY SIMULATING ACUTE EPIPHYSITIS.

DR. E. CAUTLEY showed a patient, a female, who was born on December 13th, 1900, and came under observation on December 2nd, 1901. She was the fourth child. Two had died in infancy from diarrhoea. She was fed on cow's milk and barley water during the first two months of life, and since then on condensed milk and barley water, with the addition of "Brighton Biscuits" at the age of five months. The history of the dietary is not very reliable. The left arm and shoulder had been swollen for two weeks. The child was pale, ill, and cried when moved or touched. Four teeth were out, and the two upper lateral incisors showed signs of eruption. The lower gums were normal, but the upper gums, round the teeth, were swollen and dusky red in colour. There was extensive swelling of the left shoulder, extending half-way down the upper arm. The swelling seemed to be in front of the joint and under the periosteum of the humerus. There were moderate signs of rickets, beaded ribs, and enlargement of the epiphyses, especially of the knees, which were much swollen above the condyles, and very tender. Exploration of the shoulder confirmed the diagnosis of scurvy, pure blood being obtained. In the course of two days the swelling extended down to the elbow. The child made a satisfactory recovery under anti-scorbutic diet, without drugs, but still presented considerable thickening of the left humerus, especially of the lower half. Pyrexia was slight and irregular.

Dr. C. A. SUTHERLAND suggested the possibility of fracture, secondary to the scorbutic condition, causing the thickening of the lower part of the humerus. He recommended that a skiagram should be taken. The fact that the upper arm still showed considerable immobility was to some extent in favour of this suggestion.

The CHAIRMAN remarked on the rarity of the condition simulating an epiphysitis in the upper arm and on the vertical extent of the thickening. He thought that a series of skiagrams in such cases would prove of interest.

Dr. CAUTLEY, in reply, pointed out that at first the swelling only extended as low as the middle of the humerus, and that in the course of two days it extended down to the lower epiphysis. The gradual extension downwards was not in favour of fracture, and there did not appear to be any bending of the bone, he pointed out that the thickening was most marked in the lower half of the humerus by reason of absorption taking place from above downwards, the blood last effused being the last to be re-absorbed.

Mr. F. JAFFREY showed a child, aged ten weeks, with craniotabes. When first seen, a month previously, the child was suffering from congenital syphilis and, on examining the skull, he was found to have craniotabes, which practically affected all the bones of the vertex, but was best marked on either side of the lambdoid suture. The child was at once weaned and put on grey powders and small doses of cod-liver oil. Mr. Jaffrey made a few remarks on the causes of craniotabes, and said that the best marked cases he had seen were in subjects of congenital syphilis, though he had seen the condition not uncommon in rickets.

Dr. L. GUTHRIE pointed out that many cases improved very rapidly, even as rapidly as the one brought before the Society. He believed in the association of the affection with congenital syphilis, but had seen cases in ill-developed infants, independently of either congenital syphilis or rickets.

Dr. E. CAUTLEY thought it important to have a clear understanding as to what was meant by the term craniotabes. He considered that there were several varieties of the affection. One he regarded as due to delayed development. The bones of the vertex are sometimes not ossified at birth, and remain membranous for some weeks. This is especially the case in premature infants, but occurs also in infants born at full time. He thought the present case was one of delayed ossification. To a second variety he gave the name, the Parieto-occipital Type. It is characterised by softening along the sutures, mainly the lambdoid suture. This, he said, is extremely common in infants brought up on condensed milk, and especially so when the infant is kept in close, badly ventilated rooms. Consequently it is found most often in the early months of the year. He ascribed it to a deficiency of the lime salts in the food. The text-book type, that in which scattered isolated spots of softening are found, he regarded as extremely rare, and he had never seen a case during life and verified post mortem. He had also seen very extensive craniotabes associated with congenital cerebral defects and with congenital hydrocephalus. He was extremely sceptical as to any aetiological association with congenital syphilis, beyond the general malnutrition so often present in this disease.

Dr. W. EWART discussed the tendency to primary atrophy of the tissues in connection with congenital syphilis, and suggested that the presence of an analogous process in other bones would be confirmatory of the view that the disease is a cause of craniotabes.

Dr. G. A. SUTHERLAND thought the question was not yet settled and that the book-type of the affection is not very rare, especially in the parieto-occipital region. He believed those cases to be due to congenital syphilis when the patches were circular with surrounding ossified bone. As to the mode of production, he thought that in some cases absorption took place from the outer surface of the bone.

The CHAIRMAN suggested that in view of the possibility of a connection with congenital syphilis it might be advisable to treat all such cases with mercurial preparations.

Mr. JAFFREY shortly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF OBSTETRICS.

MEETING HELD, ROYAL COLLEGE OF PHYSICIANS, ON
DEC. 20TH, 1901.

The President, Dr. W. J. SMYLY, in the chair.

A PATIENT was exhibited and paper read by Dr. A. HORNE, entitled

NOTES ON A CASE OF CÆSAREAN SECTION,
which will be found on reference to page 4.

In the discussion that followed, Dr. ALFRED SMITH said he had listened with great pleasure to Dr. Horne's case. It left nothing for criticism, but much for praise. He could say nothing more than that he congratulated Dr. Horne on the successful issue of his operation.

Dr. GLEN agreed with Dr. Horne on the risk of sepsis but vaginal examination is attended with. He thinks

the bold, good cut going right through the placenta, if it lies in the line of incision, is good surgery. The risk of soiling the peritoneum by the liquor amnii may be avoided by binding round the uterus; bringing out the womb through the abdominal incision adds to the shock. For a living child he recommends the Cæsarean section, but if the child is dead he prefers Porro's operation. Removal of the placenta is sometimes difficult, and it is advisable to swab out the cavity with hot water. Packing the uterus with gauze, and bringing a portion of the tissue through the dilated os uteri into the vagina is recommended.

Dr. W. J. SMYLY desired to add his quota of praise to Dr. Horne on the very successful result. Nothing could be better than an afebrile case and an aseptic recovery. Pelvic deformities were not often met with in Ireland compared with other countries. During his seven years' term as Master of the Rotunda he had only four Cæsarean sections and four symphyseotomies, yet from a letter he received from Glasgow he learns that one of the surgeons of the maternity had nine Cæsarean sections in nine months. In all these cases the question arises—should the woman be made sterile at the time of the operation? He thinks not. Can you choose your time for operation? If so, by all means select daylight.

Dr. HORNE, in reply, stated that he used silk sutures, he passed six of them deep through the uterine wall, but not through the lining membrane, and the superficial sutures were through the peritoneum covering the uterine incision. He neither packed nor swabbed the uterus, there having been no risk of infection. He looks on the making sterile of the patient as unjustifiable. After operation he thinks the less interference with the uterus the better. Foreign bodies introduced into it are very likely to set up after-pains.

Dr. HASTINGS TWEEDY then exhibited two ovarian cystomata. During the examination of the patient prior to operation he had no difficulty in detecting the presence of the smaller tumour, but he utterly failed to recognise the larger, though it extended to the umbilicus, and the patient was deeply anaesthetised. He advised an operation. When the patient was on the operating table and deeply anaesthetised she was again examined, but with no more satisfaction than at first. On opening the abdomen a great gush of ascitic fluid came, and he found a large cyst extending to the umbilicus, and all around a "bread and butter" mass, which he looks on as indicative of cancer. Pulling down the peritoneum he found cancerous masses connected with the loops of the intestines. The patient made an afebrile and uneventful recovery. On the Saturday after the operation she talked of going home, but in the evening of the day she was in a state of collapse, with shallow breathing, and she was pale and fallow in appearance. She got an enema and was better in the morning; she was fed for a time by enemata and quickly rallied, going home from the hospital on December 19th, 1901. The tumours are cancerous, with a considerable amount of fibrous tissue.

Dr. GLEN congratulated Dr. H. Tweedy on his honesty in declaring that he failed to diagnose the large tumour prior to operation, even under anaesthesia.

Dr. W. J. SMYLY would like to know what those present thought the tumours were if not cancerous. When ascites is present it makes the diagnosis of abdominal tumours much more difficult.

Dr. TWEEDY: Large cystic tumours are more difficult to diagnose than small tumours. He looks on the pedicle as the characteristic sign of ovarian tumours. The term "bread and butter" would be found in American literature.

France.

[FROM OUR OWN CORRESPONDENTS.]

PARIS, December 25th, 1901.

TOXICITY OF THE URINE OF TYPHOID PATIENTS AS AN INDICATION FOR TREATMENT.

At a recent meeting of the Biological Society of Paris, Messrs. Ingallbans and Dehon read a paper on the

effects of treatment on the toxicity of the urine of typhoid patients. The results are interesting, and not without value in practical medicine.

The observations were made on eight patients, of whom two were submitted to treatment by warm baths, two by cold baths, and two of them got an abundance of water to drink but got no baths. The authors found that the toxicity of the urine of those who got warm baths remained comparatively unchanged; in those who got cold baths it sensibly increased, as it did in those who drank freely but took no baths. In both the two latter classes the coefficient of urotoxine was raised considerably above that of the patients in the first class who got warm baths. There is, however, the possibility that many of the toxins that would otherwise have been passed by the first two patients were eliminated by the skin whilst the patients were in the hot bath.

Without more details it is impossible to draw a conclusion as to the relative value of the different lines of treatment adopted.

WRITING FOR THE BLIND.

The best known system for enabling those afflicted with blindness to write is that of Braille. There are however, various disadvantages connected with this method. In the first place, the blind student has to learn two alphabets, two notations of figures, and two musical notations, one for reading and one for writing. This is a long, difficult, and tedious business for both student and master. Then again, the blind student is obliged to learn to write from right to left and to read from left to right, two cerebral processes which are antagonistic. In order to read over anything he has written, the blind student is obliged to lift up the leaf of paper from between the plaques of zinc and copper and to turn it over, and when he wishes to write again, he has to reverse the process. Finally, he cannot calculate, for to do so he must read and write on the same side of the paper. A new method has lately been invented by Dussaud, which has many advantages over the system referred to. By its means the blind student writes the letters as he reads them. He has to learn only one alphabet, one set of figures, one musical notation. Thus there is an economy of half the time and fatigue in his education. He writes and reads from left to right. He can read over again what he has written, he can correct it, and he can calculate on paper. The construction of Dussaud's apparatus is simplicity itself, and will prove a boon to many of those unfortunates who cannot see the light.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Dec. 28th, 1901.

At the Society for Psychiatry and Nervous Diseases Hr. H. Kron showed a

CASE OF ARSENICAL PARALYSIS.

The patient was a girl, *æt.* 21, whose father suffered from headaches, but there was no further history of hereditary trouble. For a long time she had suffered from migraine, and had taken arsenical tabloids of 0.001 grm. On November 29th, 1899, she took about fifty pills in twenty hours on account of the unbearable headache. On the same day she had paræsthesia of the legs and back, and during the night pain in the abdomen. The

next day there was paralysis of the arms and muscles of the back and abdomen. The central nerves were free, no trouble in speaking, swallowing, or breathing. The mind was clear and there was no rise of temperature. No vomiting nor diarrhoea. The nerves and muscles of the lower extremities were painful on pressure for months. There was no electrical reaction. The menses remained absent for six months after the poisoning, and there was also considerable falling out of the hair. She was admitted into Mendel's Klinik on August 2nd. There was then renewed paralysis of the lower extremities. The right thigh could only be slightly extended outwards and abducted. The toes of the right foot could only be flexed slightly; other active movements were impossible. The tibial and crural nerves with their muscles could be excited by strong currents, but other muscles and nerves did not react. Standing and walking were impossible. All reflexes were absent. The urine contained no arsenic. The blood was normal, pulse 96 to 130. Occasionally there was præcordial distress. In the later weeks fibrillous twitching of the right thigh was present. There was now some improvement. The speaker concluded that the case was one of peripheral neuritis, lesion of the cardiac vagus, and of the motor nerve of the bladder and the splanchnic. The case was in favour of the peripheral site of the arsenical paralysis. He thought that arsenical tabloids should not be given out to patients without proper instructions, as to their use.

Hr. T. Cohn showed a patient from Mendel's Klinik, *æt.* 15. The mother suffered from an attack of fainting, and the patient was similarly affected. She lost consciousness practically without twitching and loss of memory. Nothing further could be made out as regarded epilepsy. The present illness developed three years ago, with increasing pain in the lower leg. She then complained of this and of difficulty in walking. The feet were so put down that the tips of the toes and external margin of the foot touched ground first. Both feet were in a position of equino-vagus, most of the nerves of the leg and feet were affected. There appeared to be some hypertrophy of the muscles of the calves of the legs, but against the diagnosis of anything typical was the commencement of the affection in the peroneal group and in reaction of degeneration. Probably it was a transition case like those of Oppenheim and Cassier.

The second patient shown was a woman of 34, who had probably had syphilis, and who had mitral insufficiency and stenosis. Some years ago she had some attacks, probably apoplectic, one of which was a year ago. The present condition had developed gradually. There was right-sided hemiplegia and athetoid movements in the hands and toes and mimictory movements of the hand. She had also spasm of the left side, especially of the lower extremities, and paresis. The patellar reflexes were sharp, patellar and foot clonus—Babinsky's sign. The bulbar symptoms were remarkable; salivation, difficulty in swallowing and speaking. There was also a complicated form of aphasia. There was disturbance of spontaneous speaking, and also in repeating words. Many words she was unable to repeat. She probably had some sensory aphasic disturbance. There was, therefore, a mixed speech disturbance, an aphasic and a marked dysarthritic bulbar speech. Probably there were multiple centres of brain mischief.

The *Archiv. f. Klin. Chin.*, 65/2, has an article by A. A. Kiesel on the

DIAGNOSIS OF TUBERCULOUS PERITONITIS.

The conclusions arrived at are based on fifty-four cases observed by the writer himself. The conclusions are summarised in a series of numbered theses, and are as follows:—

1. Tuberculous peritonitis in children is more frequent than is generally thought.
2. It may be taken for granted that nearly all cases of spontaneous ascites are nothing else than tuberculous peritonitis.
3. The exudation in tuberculous peritonitis is not unfrequently absorbed under general tonic treatment, so that the health of the children affected is completely re-established.
4. In most cases the disease comes on insidiously. The relatives first remark that the child is evidently, and without any cause, becoming pale and thinner.
5. Diagnosis is much facilitated by the presence of simultaneous serous pleurisy.
6. Thickening of the peritoneum (ascertained by feeling the peritoneum in a fold) may be considered the most important sign of the disease.
7. In tuberculous exudative peritonitis the fluid obtained from the peritoneal cavity is rich in albumen and of high specific gravity.
8. One frequently finds, even when the objective symptoms are insignificant, and the subjective ones good, the whole peritoneum covered by a thick layer of tolerably recent tuberculous deposit.
9. The diagnosis is most difficult in cases of chronic ascites with tuberculous pericarditis, but this affection is but rarely met with.
10. Tuberculous peritonitis begins in a rather violent manner only in rare cases.

Frangui Volk., 31/6, 1901, reports a case of

ABSCESS OF THE UTERUS AND METRITIS DISSICANS

The patient was a woman who had been treated manually for abortion. An abscess the size of a hen's egg subsequently developed in the left uterine wall, then a violent rigor came on, and the patient's condition became serious. The abscess, however, opened spontaneously into the vagina. For six weeks the temperature remained sub-febrile, and for six more the condition, both objectively and subjectively, was apparently good. Four months after the abortion, however, a necrotic piece of the uterine wall was cast off without any further consequences, the patient continuing in good health.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

OPERATION FOR TUBERCULOSIS OF THE TEMPORAL BONE IN AN ADULT.—MR. ARTHUR CHEATLE operated on a man, *set.* 27, who came to the hospital with the following history: Four months previously the patient's right ear became suddenly deaf after blowing his nose during a cold. The deafness persisted without pain, and seven weeks later he first noticed a discharge; soon afterwards he had severe pain, and he then came to the hospital suffering from a discharge from his ear and a swelling behind the auricle. Owing to the painless character of onset and the facial paralysis tuberculosis was suspected; it was also found that

he had fine crepitations at the right apex. At the operation extensive caries was found involving the bony meatus, the whole of the middle ear, the antrum, the mastoid process, and the skull over the lateral sinus and over part of the cerebellum. The bone was soft and porous, typical of tuberculosis. The affected bone was extensively removed with Hoffman's cutting forceps; the dura mater underlying the affected bone was found in a granulating condition, this was scraped with a sharp spoon, pure carbolic acid was applied to the whole area of operation, and the huge remaining cavity packed with iodoform gauze. Mr. Cheatile said the nature of the disease was suspected by reason of the painless onset and the facial paralysis together with the lung signs; he pointed out that such a condition was more frequently met with in children than in the adult. The mode of infection he thought in all probability was the inoculation of the middle ear through the Eustachian tube at a time when the cold in the patient's nose diminished his resisting power. The onset of a tuberculous affection of the middle ear was, he considered, an insidious one; deafness without pain associated with a dull red swollen and apparently bulging membrane, lasting for some time should, he said, arouse suspicion. After such a condition has lasted for some time a small perforation appears and a slight discharge occurs from the middle ear, perforation being due to the tuberculous ulceration; after perforation has occurred the internal ear through the meatus is likely to become infected with any pathogenic organism. Mr. Cheatile said that a short time ago he had seen a case in a young man with the condition he had described, but before perforation had occurred the patient's chest showed signs of tuberculosis, which condition had been certainly unsuspected; within a week of the diagnosis having been made the man nearly lost his life through a first and most profuse hæmoptysis. Mr. Cheatile was of opinion that in operating in these cases, the surgeon's manipulations being of course consistent with the patient's life, every particle of disease should be removed; the facial nerve must not be considered. He pointed out that in the case he had just operated on the facial paralysis was complete on admission, and even if such had not been the case it would have been the duty of the surgeon to have cut through the nerve if the bone around it, and intimately associated with it, had been found in a diseased condition.

The patient was much benefited by the operation, and although the resulting wound was a huge one, cicatrisation gradually and slowly took place, but a sequestrum, an inch in diameter, formed at a part of the skull over the middle fossa; this gradually separated, and sound healing of the whole wound occurred. Since then the patient has been admitted into the surgical wards with tuberculous disease of his left elbow and a tuberculous abscess in his back.

CENTRAL LONDON THROAT AND EAR HOSPITAL, GRAY'S INN ROAD.

OPERATION FOR CEREBRAL ABSCESS, FOLLOWING CHRONIC DISCHARGE FROM THE EAR.—DR. PERCY JAKINS operated on a boy, *set.* 14, who had originally been in the hospital under his care five years before; at that time he opened the mastoid antrum for chronic

discharge from the right ear. This operation (Schwartz's) was successful, and no more was seen of the lad until five years afterwards, when he came to the hospital with a large fluctuating swelling over the right mastoid; this was incised and a lot of very offensive pus escaped; the following day the boy was semi-unconscious but could be roused, the hand grip on the right side was considerably more feeble than on the left, photophobia, optic neuritis on right side, pulse 62, temperature 98°; bowels very constipated. The patient was put under chloroform, and the lateral sinus exposed to the extent of an inch and a-half; pus was seen welling up on the inner aspect of the sinus. The sinus was drawn aside and then pus freely escaped; the external wall of the sinus was found to be covered with lymph. The sinus was then laid open, and the upper end plugged with iodoform gauze to stop the bleeding. A probe was next inserted, and it went through an opening in the dura to the cerebellum; the instrument was withdrawn, and a pair of sinus forceps put in its place. These were opened, and very offensive pus welled up at once. A drainage tube was inserted, the wound lightly packed with gauze, and the patient returned to bed. His pulse during the latter part of the operation had risen to 78. Dr. Jakins said that the easier course would have been to trephine below the lateral sinus, but as there was already a perforation in the dura he did not feel justified in making another. He thought that the operation done five years ago was not perhaps the proper one for the case, it ought to have been the complete mastoid operation of Stacke instead of the partial one which was brought forward by Schwartz. He pointed out that the parents had informed him that the boy had had a slight discharge on and off ever since the first operation. About seven days before re-admission the lad had complained of severe frontal and parietal pains, shivering, drowsiness, delirium, and he constantly had cried out, "Oh, my head."

On the morning following the last operation the boy was quite conscious, his temperature had risen to 101° and his pulse to 74. He, however, was still complaining of his head. The wound was re-dressed, and was looking very sluggish. A hypodermic injection of morphia was given, and an ice cap applied to the head. Four days after operation the patient was again put under chloroform; the lateral sinus plug was removed and a fresh one inserted, as the sinus was still patent. The patient's temperature fluctuated between 101° and 104°, but dropped to normal on the following day. Three days afterwards, the temperature again rising to 104°, chloroform was again administered and the plug removed. No hæmorrhage occurred on this occasion, so the sinus was only lightly plugged. The temperature since then has been normal, and fourteen days after operation the boy was doing well; he was perfectly conscious, there was no pain or photophobia, the optic neuritis had much improved, the hand grips were equal, the constipation was better, the appetite good, and he sleeps well.

It is unfortunately a rare occurrence that we can record the fact of a man in general practice leaving a fortune behind him. Last week, however, the will of Dr. Thos. Aspinall, late of Darwen, was proved under £69,000 personality.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 1, 1902.

MCMI.

THE first year of the twentieth century has come and gone. Its contributions to medical science have not perhaps been of an epoch-making nature, but still they have been definite, and point to sure and steady progress in the future. Undoubtedly, the event of the year was the British Congress on Tuberculosis, and the event of the meeting was Professor Koch's startling declaration on the relations of human and bovine tuberculosis. His views have not as yet been regarded as definitely proved or disproved. A Royal Commission, whose constitution is such as to ensure universal respect for its findings, has been appointed, and will we trust be able to set at rest the uncertainties which surround this most important question. An event of the year, which it were well should attract to itself as much attention as did Professor Koch's communication, is to be found in the epidemic of small-pox which invaded London towards the end of July, and which shows no signs of abating. The present Government created the conscientious objector, and the conscientious objector created or helped largely to create the present epidemic. If the public at large would recognise this, if they would become a little less indulgent to the vast and noxious army of faddists by which we are beset, the epidemic could not be regarded as unattended with good. Once the public recognise that the term conscientious objector is synonymous with unconscionable neglect, the fate of small-pox in these islands will be that of rabies. Perhaps the most striking practical success of the year has been the extinction of rabies. As a result of the wise and statesmanlike orders of Mr. Walter Long, the opening of the New Year synchronises with the declaration that the British Isles are free from hydrophobia. It is a triumph of scientific government, and it is more, it is a victory over faddists. Districts of England have been visited

during the year by another epidemic, or, perhaps we should say endemic, on which a Commission at present sits, viz., arsenical poisoning. The presence of arsenic in articles of everyday use has come to be recognised not only as a possibility, but under some circumstances as a probability. The Commission issue reports from time to time, and will, we trust, be able to recommend measures which will be a complete prevention to the recurrence of such epidemics. During the last few days, a sensational report has been published, regarding what will undoubtedly be the great aim of medical men during the twentieth century—the discovery of the causation and cure of malignant disease. According to the lay press, Dr. Doyen, of operative fame, has presented in a dramatic manner, to the Academy of Medicine of Paris, the announcement that he has discovered the organism which causes cancer, and further that he has been able to produce a protective serum from it. We await the details of his communication with impatience.

The surgical advances of the year have not been perhaps so marked as in previous years. The field which anæsthesia and asepsis opened up is becoming gradually cultivated, and consequently each succeeding year sees less and less room for original work. The treatment of gastric ulcer, resection of the stomach, intestinal anastomosis, and wounds of the stomach and intestine have received chief attention. A new operation has indeed been introduced for the treatment of hepatic cirrhosis, but it is as yet too soon to do more than chronicle the fact. It cannot be denied that the unsuccessful result of the operation performed in America on the late President McKinley was the cause of much disappointment to those who looked for a triumph of modern surgery. The patient was operated upon under the most favourable circumstances—comparatively speaking. He, apparently, did well at first, but a sudden change came for the worse, from which he never rallied. At the autopsy it was found that no attempt at repair in the wound of the stomach had taken place. There was no septic infection, and it would seem as if the impact of the bullet had caused the actual death of the tissues through which it had passed.

In the realm of obstetrics and gynaecology the past year has not been attended with any notable change or improvement. The treatment of eclampsia has, perhaps, been most prominently brought forward, particularly with a view to determine the value of saline infusions with the object of promoting diuresis. The most interesting event is undoubtedly the establishment of the *Journal of Obstetrics and Gynaecology of the British Empire*. This step was received with almost universal approbation by the leading obstetricians and gynaecologists of the Empire. It is true that some influential and respected specialists did not, and do not regard the proposed journal in this manner. We think, however, that their objection is, in part, based on misconception, in part on unfounded apprehension, and that it will be removed in time. If the journal

meets with the universal support for which it looks, it will be a source of credit to Pan-British specialists, and will not interfere with existing journals. The lumbar injection of cocaine, with the object of obtaining anæsthesia during parturition, has continued to receive attention abroad. At home, we cannot say that it has received much consideration. The possibilities of the drug are so serious, and the limitations for its use are so insufficiently defined as to render it, in the minds of conservative medical men, unsuitable for experimentation.

In the world of dental surgery the two most important events have been the opening of the new buildings of the Royal Dental Hospital of London, and the recognition by the War Office of the importance of looking after the teeth of soldiers. As a result of the latter discovery various appointments have been made, including that of four dental surgeons who have been sent to South Africa.

A great advance must be chronicled under the head of anæsthesia. It is not that a new drug has been found which surpasses the existing ones, nor that a new apparatus has been designed for the administration of an anæsthetic. It is that medical opinion is commencing to recognise that the administration of anæsthetics requires care and experience, and that such can only be imparted to the student or medical man by systematic instruction. From the recognition of a principle to the realisation of it, is a less laborious task than is the primary recognition. Consequently, we hope soon to learn that regular instruction has been rendered obligatory in the case of students.

In the Army Medical Service important changes have taken place and are in course of taking place. As a result of the allegations which were made concerning a breakdown of the Royal Army Medical Corps in South Africa, a Royal Commission was appointed to enquire into the treatment of the sick and wounded. As a result, a unanimous report was issued, which stated, amongst other things, that "in no campaign have the sick and wounded been so well looked after as in this." Subsequent to and consequent on this report a War Office Committee of Experts was appointed by Mr. Brodrick. They sat, and presented a report, or rather a series of recommendations. It cannot be truthfully said that this report has been received with any great degree of favour by the medical profession at large. It is, however, admittedly, but a framework on which to hang the finished article, and with the necessary adjustment it may enable the latter to be made of the required shape. The medical profession earnestly desires the adoption of a scheme which will enable the formation of a service worthy of the British Empire. There have been enough patchwork reforms of the most insufficient and temporary nature. Completeness and finality is what is now required. We are at present on the eve of the issuing of the warrant which may have this happy result. In all probability alterations will be found to have been made with the result that the warrant will be more suited to the

requirements of the Service than was the framework to which we have alluded. If such should turn out to be the case, it will be received by the medical profession in a generous and broad-minded spirit. The Indian Medical Service also calls for reforms. It is undermanned, and in the present stress of national affairs greatly overworked. It will have to be taken into consideration in the general "settling up." The same remark applies to the Royal Navy Medical Service.

We have duly referred throughout the year to the labours of the General Medical Council, and, consequently, do not propose to dwell at any length upon them here. The event of the year has been the question of the course to be pursued by the Council with regard to the attitude of the English Colleges on the subject of preliminary scientific education. The points at issue are matters of common knowledge. They have been approached in various spirits at each meeting of the Council for the last two or three years. At last there seems to be a prospect of some definite action being taken in the matter. At the last session of the Council a committee was appointed to prepare a report on the differences which exist between these licensing bodies and the Council, which report is to be presented to the Council at a special meeting in February next. We trust that the year which is opening to-day will enable a satisfactory issue to be brought to this disturbing question. There are possibilities connected with its solution which cannot be overlooked, and which render a satisfactory settlement of the greatest importance. If the General Medical Council succeed in reaching such a settlement no one will consider that they have wasted the two years which they have devoted to it.

URETHRAL DISEASES AND THERAPEUTICAL STASIS.

THE question may well be asked whether any real progress has been made in the treatment of specific affections of the urethra. The most sanguine would hardly venture to assert that gonorrhœa is cured now in less time than of yore, if we place on one side the evil wrought by too energetic or otherwise improper methods of treatment. The most that can be said is that we are beginning to see the error of our ways, and have abandoned recourse to the so-called abortive methods of treatment which more than anything else tend to defer recovery and prolong convalescence. Knowledge in respect to the pathology and exact nature of gonorrhœa has been of slow growth. Recognised in centuries long past as a morbid entity, gonorrhœa, from early in the sixteenth to the middle of the nineteenth century came to be regarded as one of the manifestations of syphilis, and it was reserved to Neisser, in 1879, to isolate the specific organism of the disease. The bearings of his epoch-marking discovery have since been widened and extended by the researches of Metschnikoff and others in regard to the nature of infective diseases and the reaction of the organism thereto. This fact may lessen the

surprise one cannot but feel at the lack of progress in our knowledge of how to prevent or check the disease. The treatment in vogue to-day does not differ in any essential particular from that employed by our professional ancestors. Were that treatment attended by well-marked curative effects there would be no ground for complaint, but such, alas, is far from being the case. The acceptance of the bacterial origin of the disease has but stimulated practitioners to attempt to bring about a cure by the direct application of germicides to the affected mucous surface, with results which are in general negative, when indeed they are not actually disastrous. This fundamental error is based on the assumption that the discharge constitutes the disease, instead of, as it is, merely the outward and visible evidence of the conflict going on between the tissues and the invading microbe, and an effort on the part of nature to destroy it by means of the bactericidal serum. In a critical article on "Fallacies in the Treatment of Urethral Diseases," from the pen of Dr. Robert Holmes Greene, published in a recent number of the "Journal of the American Medical Association," the author points out that it is an error to suppose that urethritis is limited to the anterior urethra, his experience leading him to believe that the disease, not rarely, but generally, invades the deep urethra and prostate. This view is held by those who initiated what is now known as the irrigation treatment of gonorrhœa, their idea apparently being that the gonococcus can be killed by the direct application to it of some substance inimical to its existence, or that the soil can thereby be rendered unfavourable for its development. The treatment, it is urged, is not in accord with modern views on the pathology of infective diseases, and, according to the author, although it may render the patient more comfortable, the result is but to postpone the outcome of the struggle between the gonococcus and the tissues. If the author had something to offer us more truly curative than the methods he decries we might be willing to place the comfort of the patient and the subsidence of the principal symptoms in the background, but he comes with empty hands. To tell us that the bactericidal serum, the phagocytosis and the chemotactic action of the nuclei with the ptomaine given off by the invading bacteria, should be closely studied, sounds promising, but we are not prepared to sacrifice available methods which temper the sufferings of the victim and modify the course of the disease until these researches shall have been carried out. Dr. Greene deprecates active interference before the sixth week, and even then he lays most stress on purely hygienic measures. We are, indeed, hardly likely to get valuable hints for treatment from a critic who concludes his article by laying it down that urethritis is a disease, often serious in character, apparently established by nature or God as a punishment for immorality, calmly ignoring the fact that its ravages are by no means confined to the incontinent or the ungodly.

THE MEDICAL OUTLOOK.

WITH to-day commences the second year of the century, and if we have read aright the omens a new epoch has commenced for medicine. We have no desire to be too optimistic nor to minimise the good work done in medicine in the past; on the contrary, we hold that it is the good work done in the past that makes possible the great advance medicine is destined to make in the present century. Indeed, the promise of the advance of scientific medicine in the future rests on the recent great advance in the collateral sciences. The greatest and most beneficent function of medicine is shown in the prevention of disease. Now the province of preventive medicine is practically based on knowledge accumulated by workers in natural history, biology, and chemistry. The physician still gives quinine for malaria, but he does so with a knowledge of what malaria is and how it is brought about. Already he has advanced a step further, and seeks to banish the disease from the list of human ills. The biologist, by tracing the life history of the micro-organisms, has shown the influence for good or evil that a modification of the environment makes, and utilising this knowledge, the patient in the early stage of tuberculosis is no longer condemned to an inevitable fate but assured of recovery if certain conditions of life are conformed to. In chemistry the pursuit of knowledge for its own sake has given medicine the X-rays and added phototherapy to the armamentarium of the physician. Fortunately for humanity, information is now so quickly diffused and the schoolmaster has been so diligently at work that the sanitary conditions necessary for health have come to be generally known and appreciated; they have influenced legislation, and the poor in our large towns and country villages in the coming generation will live under hygienic conditions greatly superior to their predecessors. How medicine influences labour for the good of the individual and for the benefit of industry is strikingly evidenced by the hygienic building erected for the workers on the Simplon Tunnel, and the means of ventilating and cooling the tunnel by air-shafts, with the result that this great engineering feat is being carried out quickly and at little cost of human life. Ignorance of how malaria was spread stayed Lesseps' great Panama Canal scheme. One of the most promising signs of medical progress is the confidence, begotten of successes, with which the difficult question of malignant growths is being studied. All the aid the sister sciences can throw on the subject are sought and all submitted to the characteristic study of medicine—clinical observation. For a time in the latter decades of the nineteenth century it appeared as if the amazing progress made in bacteriology was about to lead off medicine to a bacterioid theory fatal as that of Broussais, to the neglect of the patient, and the ignoring of Sydenham's axiom—prescribe for the patient—until the feeding and hygiene of the phthisical demonstrated afresh that the individual, not the disease, was to be

prescribed for. If in the past physicians brought their art to its present condition, working with imperfect instruments for diagnosis and uncertain drugs as therapeutic agents, with little or no idea of the physiological action of the remedy, it is not unreasonable to look for a marked advance in the healing art when aided by the X-rays, chemical tests exploratory incisions, and so forth, supplemented by standardised drugs of known physiological action and the progress of the patient noted hour by hour by trained observers. The outlook is hopeful, very hopeful, for to-day medicine is aided by every collateral science. She does not resist disease single-handed, neither does she appeal to a people indifferent to her cries. If Lister told the value of antiseptics it was Tyndale who told of the germ-laden atmosphere, and how to make it aseptic—both benefited medicine and, through medicine, the world. Both made it possible for the surgeon of to-day to follow in the footsteps of such pioneers as John Bell, Sylvester O'Halleron, E. McDowell, and Marion Sims. The triumphs of medicine have but begun. Already tuberculosis is removed from the list of incurable diseases, and let us hope cancer will also soon follow. The physician who would avail himself of the fruits of scientific progress must learn something of the sister sciences. He must be a scientist, a true physician. Such a man will command respect and attain to honour. For the medical profession and its followers there is a bright future. But it must be borne in mind that every victory over disease will increase the number of camp followers—creatures who keep in touch with the medical profession to loot the camp and pillage all who come in their way. How to deal with the evil is not our present purpose, which is to show that there are good grounds for considering the medical outlook as hopeful, and for the belief that the century on which we have entered is pregnant with good for humanity, rich in blessings for all, physician and patient.

Notes on Current Topics.

Abdominal Contusions and Injuries to Viscera.

THE differential diagnosis of simple abdominal contusion with injury to subjacent viscera is one of the most anxious and onerous duties of the surgeon. The closest study of recorded cases, and the most careful investigation of the patient in a given case, fail to reveal any particular sign or signs which enable the surgeon to form a trustworthy opinion, either positive or negative. In many cases in which subsequent observation proves the injury to have been simple contusion the symptoms—shock, pain, tenderness, &c.—are so pronounced as to appear to justify an exploratory operation, and great is the mortification of the surgeon who has exposed his patient to the risks of such an operation without proper cause. Severe injury of the viscera, such as laceration, on the other hand, is not incompatible

with an absence of grave symptoms, and the too confiding surgeon may easily be lulled into a mistaken sense of security by the delusive state of the victim until the onset of peritonitis or more or less sudden collapse show that the injury was graver than had been anticipated, by which time it is often too late for operative measures to avert impending disaster. The surgeon, therefore, is confronted by two distressing alternatives. He may open the abdomen only to find that the organs are intact, or he may adopt an expectant attitude until too late for his assistance to be of avail. Of the two alternatives the former is, from every point of view, the least distressing. The risks are comparatively small, and the surgeon can comfort himself with the reflection that he has acted for the best, a balm which he cannot apply to his reputation and surgical conscience when he has overlooked the gravity of the injury and has failed, however excusably, to do his duty. The fact remains that we have no means of distinguishing between a simple abdominal contusion and one complicated by severe intestinal injury, except by means of an exploratory incision. This, to give the best results, must be performed within from three to six hours of the receipt of the injury. This being the only certain means of diagnosis, and its success being dependent in great measure on the promptness with which it is done, there are plausible reasons for urging that it ought to be the routine measure in all but the most trivial cases of contusion of the abdomen.

Fear as an Element in Disease.

FEAR has been credited with considerable influence as a determining factor in the production of, or at any rate in predisposing to, disease, not only of the nervous system but of all kinds, nevertheless it is in the department of neurology and psychiatry that the most telling and disastrous effects are met with. Fear, however, is a negative rather than a positive condition, indicating, as it does, a lack of control on the part of the higher psychical centres, associated, it may be, with undue irritability of the purely perceptive area of the brain. The foundation of all fear has for its basis a presentiment of danger. Now this presentiment is subject to extreme variations of intensity in different subjects, according to their experience, judgment, and self-control. It is curious to note that experience and inexperience often lead to the same result, though in widely different ways. Timidity in a child is the safeguard provided by nature against inexperience, and it serves the purpose, more or less efficiently, of protecting the child against contingencies which experience would recognise to be real—or the reverse. Owing to the absence of acquired control *quod* judgment in the young the effects of fear are much more violent and perturbing. Under ordinary circumstances fear, in the adult, has its limits, limits which are only exceeded when the exciting factor is of such magnitude or so unfamiliar as to overrule the judgment or to reduce the adult to the mental state of

an inexperienced child. For this reason emotional disturbances due to occult and purely psychical causes may find the adult as lacking in self-control as the child. When we consider the clinical manifestations of acute fear, their extraordinary comprehensiveness, their violence, and the perturbation of organic functions, of which they are the outward and visible manifestations, it is easy to conceive that the paroxysm leaves the organisms in a debile and prostrate condition, and brings into prominence any latent weakness in functional control. On the other hand, it may fairly be argued that the subjects of these violent emotional disturbances are thereby stamped as neurotic; indeed fear, when it reaches an extreme degree, is distinctly a pathological factor.

A New Tape-worm.

It is an acknowledged fact that the Japanese are an advancing race—indeed, it is thought by some that they form the nation of the future. One of their latest achievements has been the discovery of a new tape-worm. This addition to our intestinal parasites is described by Kurimoto in the *Sei-I-Kwai Medical Journal*, and has been christened by the imposing title of "*Diprogonopolos Grandis*. It is larger than either *tenia solium* or *mediocanellata*, being about ten metres long by ten and a half centimetres broad. Its uteri are in two sets parallel to each other, and the breadth of the individual joint far exceeds its length. On both its dorsal and abdominal surfaces are deep furrows, and its ovum differs in shape from that of other tape-worms. As everyone is aware, the new segments of the ordinary tape-worm are produced by the head, those at the distal point being the most mature; but in Kurimoto's parasite a different arrangement holds, each segment dividing, so that the old and young alternate. The symptoms due to this new variety do not differ from those caused by the common species, except that they are said to be more intense. The treatment is also the same.

The Diet in Epilepsy.

THE directions for diet in cases of epilepsy are usually limited to the avoidance of indigestible articles of food and the avoidance of stimulants. Useful, no doubt, as far as they go, they cannot be regarded as adequate or as commensurate with our knowledge of the deleterious influence of certain articles of food on the organism prone to epilepsy. It has long been held that a diet too rich in albuminoid constituents is harmful to epileptics. Clinical observation has not always confirmed the validity of this view, and, struck by the contradictory nature of the results, Schlöss undertook a series of experiments, which he published in a recent number of the *Wiener Klinische Wochenschrift*. He placed groups of epileptic patients on a strict milk and a meat diet respectively, and after six weeks he failed to detect any noteworthy effect of either regimen upon the number of attacks or the general health of the sub-

jects. Incidentally he found that the suppression of chloride of sodium had for effect to reduce the frequency of the attacks, but at the expense of the general health, marked loss of weight and strength resulting. Alcohol, in moderate quantities, he found to be devoid of injurious action. The fact that meat does not appear to be injurious to epileptics suggests the desirability of reconsidering the views on which this article of food has been placed under a ban. There can be no lack of opportunities for carrying out the necessary observations, and advantage might be taken of these selfsame observations to study the influence of quantity, as well as quality, of food. Obviously no hard and fast rules can be formulated in this direction, for in epilepsy, more, perhaps than in other diseases, it is the patient who requires treatment, rather than the disease. What we require are general rules, to be adapted to individual cases with due regard to the constitution, temperament and habits of life of the sufferer.

A New Constituent of Bone.

AN American physiologist, named Gies, claims to have discovered a new constituent of bone, to which has been given the name "osseo-mucoid," and which is said to be practically the same as the mucoid in tendon, cartilage, and other connective tissues. It not only responds to the general proteid tests, but appears to have the same solubilities and precipitative reactions as the other connective tissue mucoids, and yields the same proportion of reducing substance on decomposition with mineral acids. Furthermore, the combustion equivalents of osseo-mucoid, chondromucoid, and tendomucoid are practically identical, indicating the close chemical relationship of these glucoproteid products. It is probable, then, that ordinary compact bone contains mucin substance, and that in the process of ossification the connective tissue matrix is not completely removed. This act makes it easier to understand the accumulation of mucoid in various pathological formations in osseous tissue.

Church Hygiene.

It is a curious thing that, although we are becoming yearly more careful of the ventilation of our town halls, theatres, and similar public buildings, the arrangements for comfort in churches are as conspicuous by their absence as of yore. For centuries the clerical members of the population have been the chief opponents of advance in this direction, and we suppose that, although the clergy of to-day are more enlightened (in this country at all events), and are giving way at last to the resistless onward tendency of modern sanitation, it is but a part of the fitness of things and of the tenacity of conservatism that makes hygiene in places of worship still wanting in the twentieth century. Those cognisant of the condition of churches on the Continent will not be surprised at the report recently made to the Paris Academy of Medicine by M. Reminger, sub-director of the Pasteur Institute at Constantinople. For

months past this gentleman has been engaged in the investigation of the hygienic surroundings of a large number of churches, and he has found that "most of them are far from healthy, are lacking in provisions for ventilation—a fact which largely accounts for the frequent fainting fits of many of the congregation." This evil is not, however, confined to the churches of Europe. The United States of America possess many places of worship which are responsible for many a case of illness, especially of pneumonia and diseases affecting the respiratory system. Churches are almost notorious for their "cold"-giving tendencies, but why people should be called upon to worship in places which would be condemned hygienically if used for the purpose of holding meetings other than religious gatherings is an enigma to most of us. It is not merely our old sacred edifices that are to blame, but modern church architecture seems to still aim more at producing a cold, draughty, ill-ventilated structure than a place in which God can be worshipped in safety and comfort.

The Coroner and the Mummy.

As a fitting sequel to the amusing case recently noticed by us in these columns, we note that a correspondent wrote to the *Times* pointing out that Dr. Wynn Westcott had a precedent to go upon in American fiction. In one of Max Adeler's stories a certain Mr. Stanton once brought home six mummies from Peru, and over these, in the opinion of Coroner Maginn, an inquest should legally have been held. "They're human beings; nobody here knows what they died of. Stanton hasn't got a doctor's certificate about 'em, and I'm sworn to look after all dead people that can't account for bein' dead, or that are suspicioned of dyin' by foul play," was the Coroner's argument; but on this occasion, however, the "Supervisors" interfered, and said "the country didn't care nothin' about people that had been dead for 600 years"—which limited view of the law cost Mr. Maginn the fifty dollars he ought to have made out of those Peruvians.

Tuberculous Infection.

SOME very interesting experiments have been made by M. Nusse during the present year on the infection of animals by tuberculous disease. He draws attention to the fact that diseases attack the lower animals and human beings in different ways, and illustrates his proposition by the case of actinomycosis. Injecting a pregnant rat with human tuberculin, he found that the animal gave no evidence of having the disease and brought forth her litter, which she nourished. On examining the young, however, he made the important discovery that the females of the litter were infected, and that the males had escaped the infection—clearly a case of greater vitality resisting the disease. He concludes that after puerperal fever, measles, influenza, typhoid fever, and diabetes, there is a susceptibility to tuberculosis. With a predisposition to infection

in the individual, there is also a proclivity of the disease for certain organs. Grawitz and Manoe observe that the epididymis and apices of the lungs are the positions of predilection for the bacilli that are carried through the blood. The rarity with which the larynx and the trachea suffer from primary tuberculosis points out that tuberculosis of the respiratory organs is not always due to the exhalation of the microbes. That the intestines so seldom suffer from tuberculous disease may be accounted for by the protective influence of the intestinal secretion as a bactericide. The tonsils, whether through the blood or by infection from inspired air, are subject to the disease, which manifests itself in the ganglia of the neck, to which it is conveyed by the lymphatics. Tuberculous cows, through their milk, were found at Griesswald to convey the infection. In four autopsies, three in infants and one in an adult, all of whom had consumed the diseased milk, the mesenteric glands were found to contain tubercle bacilli. Koch's pronouncement on the innocuousness of the secretion and flesh of tuberculous animals will at least have the advantage of directing more attention to the subject than it would otherwise have received. In the face of the cases of the children and the adult mentioned above, we think there can be little doubt but that tuberculosis may be conveyed by diseased milk, and that such milk is unfitted for human use.

A Farcical Poor Law Election.

A most undesirable attitude appears to be adopted by the Keynsham Board of Guardians with regard to official appointments at their disposal. Not long ago it was necessary to appoint a new master and matron to the Union, and after due advertisement the House Committee selected from out of thirty or forty applicants. Incredible as it may seem, the guardians actually elected one of their own number, together with his wife, to fill the vacancies. To make matters worse, the terms set forth in the advertisement made previous special experience indispensable, whereas it appears that neither of the two appointed had anything of the kind. Several of the guardians have done their best to remove the reproach of this election from their Board by drawing the attention of the Local Government Board to the facts of the case. In answer to a letter of inquiry from Whitehall, the chairman stated that Mr. Dicey (the newly-elected master) took no part in the election. As to previous experience, Mr. Dicey had taken, as a guardian, an active interest in the management of the workhouse for several years. If the Local Government Board accept explanations of that unsatisfactory nature, the purity of local government will suffer a severe blow. The only instance we can recall of a somewhat parallel nature is the late election of the Medical Officer of Health for Southampton in the person of a former town councillor. In that case, however, the gentleman in question had the grace to retire from the Council prior to the election. The

same principle applies to both Southampton the great and Keynsham the little. If the best officials are to be secured for public appointments, it will be by ensuring absolutely open and above-board elections. Desirable men are not likely to go to the expense and trouble of contesting posts that are booked beforehand by personal and official interests of local candidates. It will be interesting to note the attitude of the Local Government Board in this matter.

An Abnormal Case of Typhoid.

THE following abnormal case of typhoid fever presents an interesting study. A child, ten years old, had an attack of typhoid fever. She had the typical rose rash, hypertrophy of the spleen, the typhoid temperature curve, the sero-diagnostic was perfect. At the autopsy the classic lesions of typhoid were not present; indeed, the Peyer's patches were so very slightly affected that it required a close scrutiny to detect anything abnormal in them. On the other hand, the mesenteric glands and the spleen were not alone enlarged, but they presented necrotic points on their surfaces. In this case the clinical symptoms of the disease were well marked, but the distinctive pathological lesion was wanting—a very unusual condition, the anomaly usually being the opposite state of affairs, the ulceration of Peyer's patches being well marked, and the clinical symptoms being either absent or simulating those of some other disease. Probably the enlargement of the spleen is the most constant sign of the disease in the young, but in those cases that occur late in life it may be absent. From a medico-legal point of view the case is also interesting, as it places beyond doubt the fact that there may be a typical case of typhoid in all but the characteristic lesion of ulceration or infiltration of Peyer's patches. Fortunately for mankind, the poisons which give rise to symptoms simulating typhoid are easy of detection, and they produce pathological lesions which are easy of recognition.

An X-Ray Stereoscope.

THE correct interpretation of X-ray negatives frequently presents considerable difficulty, because all parts of an object lying in different planes are projected into one, and there is practically no way of determining the order of superposition of the various planes, and of the distance that separates them. This defect of the ordinary skiagraph is readily overcome by making two stereoscopic negatives, which, when placed in a suitable stereoscope, virtually reconstitute the object in space. Every detail of the negative is seen in its proper place, the surfaces appear in their natural form, and the various planes are correctly separated from each other. The ordinary hand stereoscope is useless for the purpose, because it is too much trouble to obtain points small enough, and much of the fine detail of the original negative is lost in the reproduction. An instrument has been devised by Weigel which brings into play the prin-

ciple that when two plane pictures representing slightly different views of an object are superimposed, they appear to the eye as giving the same relief as the object itself.

Nature's Surgery.

ONE occasionally meets with remarkable instances of natural cures in dangerous conditions; we have ourselves known of a case in which a strangulated inguinal hernia, for which an operation was refused, cured itself, and, what was more curious, the resulting fæcal fistula underwent a similar cure without surgical aid. A startling instance of what may be called natural surgery was recently reported by an American surgeon named Wallace. His patient was a young man, aged twenty-two years, who had had several attacks of appendicitis. It was finally decided to operate, but twenty-four hours before the time appointed the patient passed his appendix *per anum*. It was three and a-half inches in length, and consisted principally of the mucous and submucous coats. It was perforated near the distal extremity and contained several concretions, one of which protruded from the perforation. During the attacks the tumour was in the right inguinal region. The abscess probably broke into the cæcum, carrying the appendix into the head of the colon. This was a very acute appendicitis, with perforation of the appendix, abscess formation, and necrosis of the cæcum—a most dangerous condition, which was cured by a fortunate operation of nature.

The Deadlock at Macclesfield Infirmary.

AT a special meeting of the Governors of the Macclesfield General Infirmary, held to consider a proposition of Mr. Robert Brown, to the effect that Miss Murdoch Clark, the junior house surgeon, should be given a month's notice to terminate her engagement, as the only means of saving the institution from serious injury and of securing the resumption of the service of the six doctors forming the honorary medical staff, it was decided not to give Miss Clark notice by six votes to three. Whatever may be thought of the rights or wrongs of the position which has been adopted by or been forced on Dr. Clark, there can be but one opinion as to the question of the control of junior staff appointments. Nobody at all acquainted with the working of a large hospital can doubt that appointments to these posts ought to be for the good of the hospital, *i.e.*, for its smooth and capable working in the hands of the senior staff. A lay board is influenced by a thousand matters which do not even indirectly affect the suitability of the candidate. Further, even with the best intentions in the world, they are not in as suitable a position to judge the qualifications of the candidates as are medical men. In this case, we fancy that the fact that Dr. Clark is a woman is a mere concomitant of the quarrel and not a cause of it. It so happens that she has come between the upper and nether millstones of the Governors and the staff. Whatever the origin of the objection, we learn that Miss Clark has sent in her resignation to the Governors of the Infirmary.

Formaline as a Disinfectant for the Hands.

THERE is considerable difficulty in obtaining an antiseptic solution for the disinfection of the hands, which is at once sufficient and free from objectionable qualities. Corrosive sublimate possesses the great drawback that its prolonged use is attended by marked discolouration of the nails. Creolin produces a rough condition of the skin, when used of sufficient strength. Permanganate of potash necessitates the use of oxalic acid as well, and is a troublesome process and also attended by ill effects on the skin. The desire to obtain an ideal antiseptic among American surgeons has led Dr. Charles Noble to adopt formaline, with somewhat disastrous results so far as he was concerned. After having used formaline solution for about a month, a great inflammation appeared at the end of all his fingers, involving the nails. This inflammation was so violent that serum collected under the nails, separating them from the underlying tissue, and it seemed for a time as though all the nails would be exfoliated. Under the influence of rest, together with an ointment of ichthyol, the inflammation subsided. As a consequence, however, the nails separated on an average for about one-third of their length from the distal extremity, but gradually returned to the normal condition. Dr. Noble considers that the factors concerned in the production of the inflammation were:—First, the use of formaline solution, and, secondly, its prolonged contact with the fingerends in consequence of his wearing rubber gloves. He has related his experience to teach the importance of avoiding a prolonged contact with even a dilute solution of formaline.

Epidemic of Whooping-Cough.

FROM British New Guinea we learn that the island is suffering from a severe epidemic of whooping cough, occasioned by the arrival of two white children who were suffering from the disease. The British territory lying to the south-east of the island is inhabited by Malay-Polynesians, who are closely related to the Maories, Tahitians, and Samoans. They are still in the Stone Age in the interior of the island, and, like all savages, very superstitious. With them, as with all people in the neolithic age, diseases are ascribed to witchcraft, and on the outbreak of an epidemic the savages search as diligently for the wizard as does the modern scientist for the microbe. Unfortunately the savage does not take much trouble to verify his suspicions, and all against whom there is an accusation made are almost certain to be killed until the end of the epidemic comes. The death of one or more signifies little to a people who have but recently been cannibals. For the medical profession the island possesses an interest as being the site of the beneficent labours of Dr. W. G. Lawes, who in the early years of the seventies devoted his life to weaning the tribes from cannibalism and teaching them the arts of peaceful industry. He also commenced the onerous task of producing a vocabulary and grammar of the principal languages spoken on the island.

and of introducing written symbols. He died in 1874, worn out in his self-imposed duties, after securing a territory of almost 1,000,000 acres for the Empire.

A Medical Hero.

THE subscriptions to the William Smyth Memorial Fund continue to come in satisfactorily. Among those most recently announced is a handsome sum collected on the London Stock Exchange, and a contribution has been sent in from the students of the School of Physic of Dublin University, where the late Dr. Smyth graduated. We are glad to be able to announce that the Right Hon. Arthur Balfour has procured a grant of £200 from the Royal Bounty Fund. In the words of our contemporary, the *Daily Express*, "we sincerely hope that the admiration which has been excited by the act of the brave doctor who surrendered his life to save the fever-stricken folk of Aranmore will bear fruit in yet more numerous subscriptions."

Freezing for Typhoid.

THE American correspondent of a London daily paper lately announced the fact that a new cure for typhoid and all other fevers had been discovered, and experimented with successfully. The cure consists in placing the patient in a specially constructed refrigerator and "freezing" the fever out. The discoverer of the new method is said to be a medical man in New York. The patient is deposited in a long rubber bag, with "auxiliary ice pockets," wrapped up in a wet sheet and blanket. In addition to this ice is closely packed about him, and he is kept in the refrigerator until nearly frozen. It is declared that this treatment results in an immediate drop in the patient's temperature of about 5°, and that it keeps decreasing until the normal is reached. We should be inclined to suspect that the decrease in temperature would be much more marked than the correspondent or the inventor believes. Undoubtedly the fever would be "frozen out," and most probably the patient also.

Costume Deformities.

CERTAIN conclusions concerning the modifications produced by modern clothing can be drawn by comparing photographs of the human figure taken by travellers in countries where little or no clothing is worn, with the average civilised human figure. Some of the results obtained by this method were recently detailed in an American contemporary by Bradford. The present method of supporting the stockings exerts a strong pull on the waist, borne in the case of women with full hips by the pelvis, but in children mainly on the thorax, and is at times too great a strain on the growing muscles. The injury to the full shape of the neck which comes from clothing is seen in the long, thin neck, with weak muscles and slight subcutaneous adipose tissue, and which results from the binding of the neck by collars, stocks, and neckbands. Among savages heavy neck ornaments have the same effect, weakening and checking the normal development of

the trapezii and sternomastoides, and, by limiting the normal fatty tissue, often making the clavicles unduly prominent. This defect is so frequently reproduced in art that it might be looked upon as a type to be admired, were it not that it is clearly the result of a lack of normal development. The injurious effect of clothing upon the shoulders is seen when the full development of the muscles is prevented and the shoulders are pulled forward, producing the common round-shoulder deformity. Naturally, the effect on the trunk is most noticeable from the effects of corsets. This effect has become so common as to lead to false standards in art as to what is the correct figure. To remove the faults which have thus gradually introduced themselves, it is necessary to determine normal standards, and to make such standards known. The standard furnished by Greek art might be accepted as a model, but, lest it be discarded as antique, its reliability should be reinforced by examination of figures uninjured by clothing, hard labour, or suffering. From investigation it appears that exaggerated fullness of the hip, disproportionate leanness of the legs and lower thighs, the flattened chest, the narrow waist, and the long neck are costume deformities to be avoided in a healthy civilisation that seeks to preserve what Nature gives.

PERSONAL.

AT the end of the session of Special Instruction at the Royal Naval Hospital, Haslar, last week, prizes were awarded to Surgeons A. T. Gailleton, M.B., and T. B. Shaw, M.B., with appointments to H.M. ships.

MR. EDMUND OWEN, F.R.C.S., Surgeon to St. Mary's Hospital, Paddington, succeeds the late Sir Wm. MacCormac, Bart., as Consulting Surgeon and Surgeon-in-Chief to the French Hospital in London.

DR. H. M. MACNAUGHTON-JONES will deliver an address to the Cork Medical Society, on Monday, January 13th. The title of his address is "An Analysis of Some Recent Methods in Gynecology."

MR. RICHARD J. H. SCOTT and Mr. Frederick K. Green, senior surgeons to the Royal United Hospital, Bath, have resigned their appointments after 20 years' service. The resignations have been accepted with great regret by the Governors.

DR. JOHN WOODMAN, who has recently resigned the post of medical officer to the Exeter city workhouse after 35 years' service, was last week granted a superannuation allowance of £64 per annum. A motion of appreciation of the services of Dr. Woodman was unanimously passed by the Guardians.

THE committee appointed in connection with the proposed memorial to the late Professor Alfred Hughes have collected the sum of £1,800, inclusive of £1,000 given by Mrs. Hughes. This amount is to be handed over to the Cardiff College Council to provide an "Alfred Hughes Memorial Medal" to be awarded annually in the class of anatomy at the college and also to endow the anatomical museum of the college.

Manchester.

[FROM OUR OWN CORRESPONDENT.]

STETHOSCOPES, ANCIENT AND MODERN.

At the December meeting of the Medical Society, Dr. Harris exhibited a most interesting collection of stethoscopes. There seemed to be hundreds of instruments of all shapes and sizes on the table. There was an original Laennec, as described in that author's first publication in the year 1819, and others as modified and described by him in 1826. These resembled a rolling-pin one foot long and $1\frac{1}{2}$ inches in diameter, made in two portions, and perforated by a bore with a small diameter. Then came the modification described by Williams in his "Physical Signs of Diseases of the Lungs and Pleura" in 1828; and also Piarry's combined stethoscope and fleximeter, described in "La percussion medicale" in the same year. The flexible stethoscope seems to have been first used in uniaxial form about the year 1834, while the binaural instrument dates back as far as 1851. One remarkable "binaural" was that of Williamson, which was composed of two bits of lead pipe and a tube of wood ending in a chest-piece. Dr. Harris has made a number of experiments dealing with the conducting power of different stethoscopes, and these will be published in due course. In the meantime he made it clear that sounds can be conducted either by a solid rod of wood or other material, or by a column of air contained within a tube. In the ordinary tubular stethoscope of wood, metal, or vulcanite, both methods of conduction are employed, while those whose the flexible instrument rely on a column of air alone. Many stethoscopes have been built with the idea of forming a resonating chamber as well as a conductor. This was condemned, and it was held that the instrument should be a conductor alone. The phonendoscope accordingly must be looked upon with disfavour. Dr. Harris could not state that any one pattern was the best. The physician must choose one to fit his own ear, and must never use it as a prop for the head!

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE SMALL POX EPIDEMIC.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The optimistic sentence with which you end your leader in your issue of to-day, December 25th, no doubt applies to London, or you would not make the statement; but it certainly does not apply to the home counties outside the metropolis, either in the urban or rural districts. There can be no doubt that the whole country, in consequence of the continued neglect of vaccination and re-vaccination, is placed in danger of involvement in an epidemic of terrible proportions. This has now been forcibly brought home to me here by the fact that several cases of small-pox have to-day been notified in the village on the outskirts of which I have a residence. This village is Meadvale, overlooking Earlswood Common, and within the boundaries of the borough of Reigate, twenty-one miles from London. The Sanitary Authority is taking steps to prevent spread of the disease, but since one of the cases has remained unrecognised for many days—mistaken for chicken-pox—it is impossible to say how far these measures are likely to be attended with success. The households of the wealthier residents have mostly been vaccinated, but there still exist among the working classes and poor a great number of unvaccinated infants, and a still greater number of older children and adults, who have not undergone re-vaccination. An anti-vaccination league, with its headquarters at Dorking, has many adherents here and throughout the county; whilst no adequate attempt has been made here or elsewhere to bring home to the mass of the people the necessity for precaution. In accordance with the recommendation of the Local Government

Board, the various Boards of Guardians have published a placard giving advice and information and announcing the provision of gratuitous vaccination and re-vaccination. But the classes in question will not, as a rule, call in the vaccination officer, and they will not or cannot walk a mile or two, dragging their children with them on the chance of finding him at his surgery. If they do not need persuasion many of them will not put themselves out of the way in the least in this matter. Whether the country shall escape the danger which threatens it or whether the danger shall be minimised depends almost entirely upon the foresight and activity of local authorities. They need rousing; perhaps you can help to do it. A house-to-house visitation ought to be organised and a vaccination station opened in every urban ward and village at which an officer should be on duty at hours when the people could attend and bring their children without loss or inconvenience.

To the burden of sorrow and sacrifice placed upon us by the war in South Africa, we do not want added a visitation which would so increase the nation's trouble; and when one reflects that in efficient vaccination and re-vaccination we have the certain means of preventing this, one feels inclined for once to reject the ordinarily wise caution—*surtout pas trop de zèle*, and to do what may seem too much rather than risk the consequences of doing, by chance, too little.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery, Earlswood Common,
Dec. 25th, 1901.

Obituary.

DR. C. H. W. ELLERMAN, ROTHERFIELD.

THIS gentleman, whose bicycle accident we recorded last week, died the following day, and was buried on Saturday with every outward mark of esteem on the part of the inhabitants. An enormous number of floral tributes were sent by friends in the profession, and by public bodies and patients with whom he had been associated. For many years past he had held the honorary appointment of Surgeon Lieutenant to the "G" Company, 1st Cinque Ports Volunteer Rifles, and the members of the corps and hundreds of the public paid their last token of regard at his grave. Deceased was but thirty seven years of age, and sincere regret has been evinced at his untimely end.

DR. WILLIAM WATSON, ROCHESTER.

THE death from apoplexy is announced of Dr. Watson, medical officer of health for the City of Rochester. The deceased was about 50 years of age, and held several local public medical appointments which thus become vacant, including that of medical officer to the port sanitary authority of the Medway. He was a silver medalist of the Society of Apothecaries, and held the honorary post of surgeon-lieutenant to the 4th V.B. Royal West Kent Regiment.

DR. ROBERT CROMIE, CLOUGH.

WE regret to announce the death of Dr. Crombie, of Clough, who was well-known in the North of Ireland. The deceased medical man took his degree of Master of Surgery in Glasgow University in 1834—some sixty-seven years ago. Afterwards he settled down in the district of County Down, with which his name has so closely been associated, and where he enjoyed an extensive practice for a lengthened period. We understand that one of his sons is Mr. Robert Cromie, the popular novelist.

Naval Medical Appointments.

THE session of special instruction at the R.N. Hospital, Haslar, terminated on December 21st, when the following surgeons received appointments to H.M. Ships. Prizes were awarded to Surgeons A. T. Gailleton, M.B. (silver medal and books) and T. B. Shaw, M.B. (microscope). Surgeons in order of seniority:—T. B. Shaw, M.B., 6,014 marks; A. T. Gailleton, M.B., 5,731; G. S. Davidge, 5,121; P. T. Nicholls, 4,997. P. L. Crosbie (entered under special Admiralty regulation).

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

MR. C. H. S.—Approved and sent.

DR. A. W. (Liverpool).—The Editor of the special department referred to is absent for a few days. You will receive a private note on his return this week.

TRIONAL FATALITIES.

A NUMBER of cases of fatalities from the use of trional and sulphonal have been recorded. Special warning has been given that abdominal distress and urinary derangements, including hematuria, porphyrinuria, indicate trional poisoning of a very grave character, and that trional, even in so-called safe doses, may give rise to serious and even fatal toxic effects.

PERPLEXED.—It has been laid down that the nature of the demand of a physician for medical services rendered without a special contract therefor is simply an implied promise to pay what such services are reasonably worth, and the proper action for their recovery is what is called *assumpsit* for such compensation as may be shown by the evidence that the physician rendering the services ought to receive. This demand, in the absence of a special contract as to what shall be paid, is an open account.

CAPT. C.—Your suggestion is ingenious, but has been anticipated, as you will find on application to any surgical instrument maker.

THE INTERNATIONAL MEDICAL CONGRESS IN 1903.

From letters received there would appear to exist some misapprehension as to the time and place of meeting of the next International Medical Congress. Hitherto these meetings have been usually held in August, but as Madrid has been decided on, a meeting there in the "dog days" would be insufferable, and we believe the spring will be fixed upon. The question of military hospitals will become a prominent feature of discussion, and all the army medical departments are being asked to send a representative. Our own department will probably be represented by its Director-General, Surgeon-General Taylor.

OPPIDANS (Leicester).—The term "podagra" is confined to regular gout, and does not apply to the abarticular or irregular varieties of the malady. A more generally applicable name would be gouty arthritis. Both neuritis and cold extremities are well-recognised gout phenomena. The surgical treatment of tophi has never been practised to any great extent, probably on account of the tendency to slow healing on the part of the uratically infiltrated tissues. There is no evidence that gout may possibly be a microbial manifestation, although recent research has pointed to the probability of such an origin in the case of rheumatic and perhaps of rheumatoid arthritis.

DR. HARTIGAN.—There is no hospital which gives instruction in all the subjects you mention. It is not desirable, and ought not to be possible for such a one to exist. We do not understand your allusion to a three months' course.

AN UNUSUAL CASE.

Messrs Roget and Weil report the case of a vigorous adult male who, in the plenitude of his health, was suddenly seized with gangrene of his eyelids. The attack was neither preceded nor accompanied by conjunctivitis nor any lesion of the eyelids. It commenced by a simple oedema of the lids, and in four days the temperature rose to 104 deg. F.; there was no pain, but a strange feeling of tightness in the skin of the face; he suffered from anorexia and albuminuria. The case is one of those of which, in 1870, Druitt wrote; it is now known to be due to an acrobic microbe, and usually runs an active course.

M.L.S.—The only disadvantage of the nitrous oxide and ether method of anaesthetisation is that it requires somewhat complicated and expensive apparatus and expert skill to administer it, but its general adoption would necessarily lead to the systematic instruction in anaesthetics, and would so far tend to make expert anaesthetists.

Meetings of the Societies, College Lectures, &c.

LONDON.

THURSDAY, JAN. 2nd.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Clinical Cases will be shown by Mr. Edmund Boughton, Dr. L. Guthrie, Mr. F. Jaffrey, and others.

BONTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Papers by Mr. C. E. S. Phillips, "On the Function of an Auxiliary Electrode in X-Ray Bulbs," and by Mr. Prosper H. Marsden, F.R.S.,

"On Radiography Applied to Dental Surgery." After which Mr. H. W. Cox will demonstrate a New Method he has devised for exciting Several Tubes simultaneously from One Coil.

FRIDAY, JAN. 3RD.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (at the West London Hospital).—8.30 p.m. The adjourned discussion on Mr. T. R. Atkinson's paper on "Small-pox" will be opened by Dr. Dobson with a paper on "Glycerinated Calf-Lymph." A proposal will be moved in the following terms:—"That the time has come when the Government should exercise control in the manufacture and sale of vaccine lymph, and should endeavour to maintain a definite standard of purity and strength."

Appointments.

DOBSON, MARGARET B. AUSTIN, M.B.Lond., a Medical Officer at the Lincolnshire County Asylum at Bracebridge.

FERRIER, DAVID, M.B., B.Ch., House Surgeon to the Salisbury Infirmary.

GEDGE, A. S., M.R.C.S., L.R.C.P.Lond., Medical Officer for the Fifth District of the Devon Union.

JAMES, HERBERT, L.R.C.P.Lond., M.B.C.S., Resident Medical Officer to the Swansea General and Eye Hospital.

MOWAT, GEORGE, M.B., Ch.B.Aberdn., Senior House Surgeon to the Royal Infirmary, Wigton.

PRESTON, L. L., M.B., B.S.Durh., Medical Officer of Health for St. Helena, Hants.

ROBINSON, G. A., M.B., B.S.Durh., Junior Surgeon at the Samaritan Hospital for Women, London.

RUSSELL, R. HAMILTON, F.R.C.S.Eng., Surgeon to In-patients at the Alfred Hospital, Melbourne, Victoria.

SANDILAND, DIGBY S., M.R.C.S., L.R.C.P.Lond., Junior Resident Medical Officer to the West Ham Hospital, Stratford.

SMITH, OSWALD, M.B., B.S.Edin., House Physician to the Salisbury Infirmary.

STANSFIELD, H., M.B. Vict. Univ., Medical Officer for the District of Clayton, Yorkshire.

TOD, HUNTER, F., M.A., M.B., B.C.Cantab., F.R.C.S.Eng., Assistant Surgeon to the London Hospital.

WINTER, W. H. T., M.B.C.S., Medical Referee under the Workmen's Compensation Acts for the Wolverhampton County Court District of Circuit No. 25.

Vacancies.

District Asylum, Mullingar.—Female Junior Assistant Medical Officer. Salary £100 per annum, with board, furnished apartments, attendance and laundry. Applications to Resident Medical Superintendent. (See advt.)

Donnybrook Royal Hospital for Incurables.—Resident Medical Officer. Salary £150 per annum, with board and furnished apartments. Immediate application to J. J. Thompson, Registrar. (See advt.)

Durham County Asylum.—Junior Assistant Medical Officer. Salary commencing at £140, with board, laundry and attendance. Applications to the Medical Superintendent, County Asylum, Winterton, Ferryhill.

Edinburgh Royal Infirmary.—Pathologist. Salary £400 per annum. Particulars as to the hours, duties, &c., of William S. Caw Treasurer and Clerk.

Lanark County Asylum, Glasgow.—Third Assistant Medical Officer and Pathologist. Salary £120 per annum, with board, residence and washing. Applications to the Medical Superintendent at the Asylum, Hartwood. (See Adv't.)

Noble's Isle of Man General Hospital and Dispensary, Douglas.—Resident House Surgeon. Salary £32 per year, with board and washing free. Applications to Frederick B. Fleming, 25 Athol Street, Douglas, Isle of Man.

Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary begins at £120 per annum, with board (no liquors found), lodging, and washing. Apply by letter to the Medical Superintendent.

Stockton and Thornaby Hospital, Stockton-on-Tees.—House Surgeon. Salary £250 per annum, non-resident. Applications to H. G. Sanderson, Secretary.

Westmorland Consumption Sanatorium.—Resident Medical Officer. Salary £150, all found. Applications to Dr. W. B. Parker, Kendal, Westmorland.

Worcester County and City Asylum.—Junior Assistant Medical Officer. Salary commencing at £140, rising to £160, and all found. Applications to the Medical Superintendent, Powick, Worcester.

Births.

CUTFIELD.—On Dec. 26th, at Merton House, Ross, the wife of Arthur Cutfield, B.A., B.Sc., M.R.C.S., of a son.

WALKER.—On Dec. 29th, at 39 Worple Road, Wimbledon, the wife of George Walker, M.R.C.S., L.R.C.P., of a daughter.

Marriages.

MARTIN-ROLFE.—On Dec. 21st, at St. Mary's, Bryanston Square, London, W., John Middleton Martin, B.A., M.B., B.C., D.P.H.Cantab., to Louisa Margaret, youngest daughter of the late Robert Holmstedt Rolfe.

Deaths.

ISACKE.—On Dec. 27th, at Orotava, Teneriffe, Matthew William Stuart Isacke, M.B.C.S., L.R.C.P., third son of Colonel Henry W. Isacke, retired, Royal Artillery, aged 30.

MASON.—On Dec. 29th, at 1 Albany Road, Stroud Green, London, N., J. Wallis Mason, M.B.C.S.L.Eng., aged 79 years.

NEALE.—On Dec. 29th, at Mountmellick, Queen's County, William Neale, M.D., J.P., aged 53 years.

A Clinical Lecture

ON

SOME CASES OF CIRRHOSIS OF THE LIVER

WITH ASCITES, INCLUDING ONE OF BANTI'S
DISEASE, TREATED SURGICALLY BY THE
ESTABLISHMENT OF A COLLATERAL
CIRCULATION.

DELIVERED AT THE WESTMINSTER HOSPITAL,
DECEMBER 24TH, 1901.

By WILLIAM MURRELL, M.D., F.R.C.P.,

Physician to the Westminster Hospital; Joint Lecturer on Medicine, Lecturer on Clinical Medicine; and Examiner in the University of Glasgow.

THAT the treatment of ascites due to cirrhosis of the liver by ordinary medical measures such as the administration of hydragogue purgatives, diuretics, or diaphoretics is unsatisfactory is a well established fact. Even paracentesis is merely palliative for the ascitic fluid speedily reaccumulates, and after a succession of tapings the patient usually dies of exhaustion or some intercurrent mischief.

The operative treatment of these cases by the establishment of a direct communication between the portal and systemic circulations is more hopeful. It is to Dr. David Drummond (1) and Mr. Rutherford Morrison, of Newcastle-on-Tyne, that we are indebted for making the suggestion in a form to ensure its general adoption and for putting the operation on a firm scientific basis. Dr. Drummond noticed that in many cases of cirrhosis of the liver where ascites was absent vascular adhesions connecting the viscera with the parietes were found, and it occurred to him that an artificial extension of the natural process might be attended with beneficial results. In some cases the enlargement of the normal channels of communication between the two systems suffices, but in others adventitious aid by the establishment of an accessory circulation is necessary. This may be accomplished in many ways, and adjacent peritoneal surfaces over the liver have been scratched, or the spleen has been fixed in the abdominal wound. The plan commonly adapted is that of sewing a portion of the omentum to the anterior abdominal wall.

Professor Talma, of Utrecht, is said to have suggested the operation in 1887 or 1888, but he published nothing on the subject until much later.

Van der Meulen performed the operation in 1888, and the patient died in a few hours of shock. Scheiky made another attempt in 1889, and the patient died on the fourteenth day of peritonitis. These cases were not published.

Th. Lens (2) performed the operation on June 6th, 1891, at the Military Hospital, Paramaribo, Dutch Guiana, the patient being a negro, *æt.* 61, named James Charles Anon. There was an alcoholic history, and the diagnosis was "cirrhosis hepatis atrophica." He had well-marked ascites, and suffered much in consequence from dyspnoea. His pulse was weak and

frequent and his general condition was unsatisfactory. An incision was made to the right of the umbilicus, and a fold of the omentum was attached to the edge of the wound with thin silk. The wound healed by first intention, there was no elevation of temperature, and the patient felt quite well a few days after the operation. The ascites returned, and the patient had to be tapped several times, although the intervals between the tapplings increased as the collateral circulation improved. The patient died on November 24th, apparently of general weakness. At the post-mortem examination it was found that the blood vessels were greatly increased in size, and that the omentum was "thick and rich in blood." The paper is entitled: "Hechting Van Het Omentum Majus aan den Buikwand bij Cirrhosis Hepatis Atrophica," and is dated December 31st, 1901. It is illustrated by two blocks from photographs showing the post-mortem appearances.

The foregoing cases seem to have attracted no attention, and were unknown to Drummond and Morrison at the time of the publication of their paper.

Rutherford Morrison's first operation (3) was performed on September 3rd, 1894, the patient being a woman, *æt.* 42. There was no alcoholic history, and the liver was smooth on the surface, and not larger than usual. She lived nineteen months, and was tapped sixty-nine times. She died of hæmatemesis, and no post-mortem examination was obtained. Morrison's second operation (4) was on October 22nd, 1895, the patient being a woman, *æt.* 39. The liver was typically cirrhotic, with much fatty degeneration. The patient improved in health, grew stout, and for two years led an active and busy life. She then developed a ventral hernia, for which she was operated on by Morrison on October 5th, 1897, and died two days later, an autopsy being obtained. Morrison's third case (5) (January 12th, 1897) was a man, *æt.* 42, who had hepatic cirrhosis, enlargement of the spleen and ascites. This was successful, and in January, 1899, the patient was so well that he was passed by the medical referee of a well-known insurance office as a first-class life.

Professor Talma (6) operated on a boy, *æt.* 9, suffering from enlargement of the liver and spleen, with ascites and kidney mischief. There were three operations. In the first laparotomy the exploratory incision was followed by gaping of the wound and prolapse of a portion of the omentum, which had to be excised. In the second operation the remainder of the omentum was stitched to the abdominal parietes. In the third operation the inferior margin of the spleen was tucked in between the skin and the peritoneum. The patient made a good recovery, and a year later was active and well. The title of Talma's paper is "Chirurgische Oeffnung neuer Seitenbahnen f. das Blut der Vena Porta," in other words, "The Surgical Opening of a new side-track for the blood of the Portal Vein."

Warrington Haward (7) of St. George's, in August, 1897, operated on a woman, *æt.* 49, the subject of calcification of adherent pericardium, enlargement of the liver from chronic congestion and ascites. The relief was temporary, and the patient died a year later. Dr. Ewart showed the specimen at a meeting of the Harveian Society of London on April 6th, 1899.

Alfred Egon Neumann (8), of Berlin, on November 2nd, 1898, operated on a man, *æt.* 45, who had a splenic tumour and ascites. There was no return of the ascites six months later.

Robert F. Weir (9), of New York, operated on November 4th, 1898, on a patient under the care of Dr. S. W. Lambert, a man, *æt.* 43, a wine taster, with a marked alcoholic history. The liver dulness extended 3½ ins. below the ribs, and the spleen was much enlarged. He had been tapped many times. The omentum was stitched on each side of the abdominal wound with catgut sutures. In addition the antero-superior surface of the right lobe of the liver, the corresponding diaphragmatic part of the peritoneum and the parietal peritoneum adjoining the wound were freely scraped with the sharp point of a steel hatpin. The patient did well for three days, but his pulse then rose, and he complained of much pain in the lower part of the abdomen. He died on the fifth day, and at the post-mortem examination extensive peritonitis was found, especially in the pelvis.

Rolleston and Turner (10) have recorded two cases operated on at St. George's Hospital. The first, in July, 1899, was in a man, *æt.* 45, in whom there was an old history of syphilis. There was ascites, and the spleen was enlarged but not the liver. The patient derived much benefit, and six months later was alive and well. The second patient was a Frenchman, *æt.* 52, who had indulged freely in *vin ordinaire*, and who had ascites. The operation was performed in July, 1899, and in the following November he was in bed with distended abdomen and oedema of the legs.

Walter Spencer operated on the first of my cases on February 20th, 1900, the patient being a girl, *æt.* 19-20. We published a provisional account (11) of this case, and the subsequent history with the post-mortem appearances as observed eighteen months later is now given (Case I.). Spencer operated on the second of my cases on October 29th, 1901, and the history of the case is appended (Case II.). My third case was operated on by Spencer on November 28th, 1901. The patient was a woman, *æt.* 50, with a somewhat indefinite alcoholic history. There was much ascites but the liver was but slightly nodular. A provisional account of this case is now given (Case III.).

Charles H. Frazier (12) of Philadelphia, on July 25th, 1900, operated on a man, *æt.* 45, who had contracted syphilis some years previously, and who had always indulged freely in alcohol. He was not a very favourable subject, for in addition to enlargement of the liver and spleen with ascites, his heart was enlarged and he had a systolic murmur audible over the whole præcordia, whilst the urine contained a trace of albumin with a few pus and blood cells. The author endeavoured to perform the operation under a local anæsthetic, but after opening the peritoneal cavity the manipulation caused so much pain that ether had to be administered. Convalescence was uninterrupted, and the patient suffered no ill effects. An account of this case was read before the Philadelphia Academy of Surgery in December, 1900, and the patient was then no longer bedridden and was able to get out daily.

Mansell Moullin (13) has performed the operation in five cases. Two of the patients died, one four weeks after the operation of pleurisy, the other one week after from exhaustion. The other three patients were discharged relieved. One was lost sight of and the other two were alive and well two years after the operation.

This is an abstract of twenty-one cases which I have verified, but the list is not complete. Bossowski operated on a girl of nine for cirrhotic liver, and the ascites developed less rapidly after the operation. Dr. Drummond informs me that Mr. Morrison has had another successful case, which is not yet ripe for publication. Dr. Ewart has had a second case, which he proposes publishing in due course. I have heard of an incomplete case in Glasgow which terminated fatally and of two cases in Edinburgh. Assuming this information to be correct, it would bring up the list to twenty-seven.

The following are the particulars of my cases:—

Case I.—J. H., a girl, *æt.* 19, was admitted to Westminster Hospital on November 7th, 1899, suffering from anæmia and amenorrhœa. She stated that she had been

anæmic for two years, and for the last eighteen months had been at home doing nothing. She had never been quite regular, and for seven months the catamenia had been absent. There was considerable oedema of the lower extremities, but there was no ascites, she was not pregnant, there was no albumin in the urine, and there was no leucorrhœa. She did not present an alcoholic appearance, there was no history of alcoholism, and the case was apparently one of oligocythæmia with considerable oligochromæmia.

The blood was of fair colour, but appeared to be thinner than normal. The red blood corpuscles numbered 3,830,000 per cubic millimetre. The colourless blood corpuscles were 3,000 per cubic millimetre, chiefly lymphocytes and finely granular oxyphile polynuclear leucocytes.

She was ordered five grains of dried sulphate of iron in pill three times a day with a drachm of sulphate of sodium in hot water every morning. This was continued for a fortnight, but although she improved in strength and colour the menstrual function was not restored. The iron was continued, and on December 13th she menstruated, the period lasting two days. She left the hospital on the 17th apparently well.

On January 9th, 1900, she was readmitted. She stated that a few days after leaving the hospital she had a bad cough and sore throat, which kept her in bed for a fortnight. On admission her temperature was 104° F. and the urine contained much blood and albumin. She had a soft apical systolic murmur conducted outwards to the axilla and round to the angle of the scapula. Her abdomen at the level of the umbilicus measured 34½ ins. It was resonant in front and on the right side, but on the left there was dulness extending from the groin to the lower margin of the ribs, and laterally from the flanks to within two inches of the umbilicus. Nothing was discovered on rectal examination and there was no indication of an ovarian cyst. There was a large quantity of fluid in the abdomen, probably confined by adhesions. The temperature during the first week always reached 101° in the evening, but there was no indication of tuberculous disease either in the lungs or in the larynx.

An examination of the blood showed hæmoglobin, 65 per cent.; erythrocytes, 3,450,000 per cmm. of good size and shape; leucocytes, 7,000 per cmm., of which 54 per cent. were finely granular oxyphile cells and 3 per cent. coarsely granular oxyphile cells. The remaining 43 per cent. was made up of small cells having a single pale nucleus, which nearly filled the cell and was surrounded by a narrow zone of fine granules staining deeply with methylene blue. They were about the size of lymphocytes, although they differed from them in many important respects.

The patient passed daily about 30 ozs. of urine of sp. gr. 1028, containing nearly one-half albumin and much blood. No casts were found, and the urea estimation gave 2.5 per cent. The abdomen continued to increase in size, and at last became so distended as to cause the patient considerable discomfort. She was feeble, and her general condition was unsatisfactory. Much doubt was experienced as to the diagnosis, but it was regarded provisionally as a case of lymphatic leucæmia, and as such was published.

On January 27th Mr. Spencer made an incision one and a half inches in length midway between the umbilicus and the pubes, from which about eight pints of slightly blood-stained fluid were drawn off. On exploration with the hand no disease of the abdominal viscera could be detected. A large glass drainage tube was inserted in the abdomen and from this there exuded on the 28th, 34 ozs.; on the 29th, 25 ozs.; on the 30th, 45 ozs.; and on the 31st, 30 ozs. of blood-stained serous fluid. The tube was withdrawn on February 5th, and the wound was allowed to heal. On February 12th the spleen was found to be enlarged, its lower edge being felt two inches below the ribs. The fluid in the abdomen gradually re-accumulated; the urine still contained large quantities of albumin, and the patient's general condition once more assumed a very unsatisfactory aspect.

It was now determined to endeavour to establish a collateral circulation on the Drummond-Morrison

method, and on February 20th Mr. Spencer attached a piece of the omentum about two inches square to the anterior abdominal wall by kangaroo stitches. The vessels within the abdomen were congested and the veins were widely distended. On March 14th the superficial abdominal veins were noted to be larger. The wound was practically healed and there was no return of the distension of the abdomen. The mitral regurgitant murmur was more marked, and in addition there was a loud systolic murmur heard most distinctly over the left second intercostal space and adjacent portion of the sternum. The albumin had disappeared from the urine.

On April 19th the report of the patient's blood condition was as follows: Hæmoglobin, 65 per cent.; erythrocytes, 3,000,000 per cubic millimetre; leucocytes, 4,640 per cubic millimetre; finely granulated oxyphile cells, 56 per cent.; coarsely granular oxyphile cells, 6 per cent.; hyaline cells, 20 per cent.; and lymphocytes, 18 per cent. Hæmoglobin value of each corpuscle, 100 per cent. The erythrocytes were irregular in size and shape.

The patient gradually improved in health and strength and was discharged on April 19th. She was seen again on June 1st and stated that she felt perfectly well.

On June 30th, 1901, sixteen months after the operation, she was admitted for the third time. She stated that until six weeks previously she had been in good health, but that since then she had been gradually getting weaker. Her abdomen measured 38 inches at the umbilicus and contained much fluid. There was a ventral hernia about an inch and a half below the umbilicus corresponding to the site of the introduction of the tube. The temperature was persistently elevated and varied at night from 102° to 103°. Her red blood corpuscles numbered 2,700,000 per cmm., and the white 3,360, the hæmoglobin value of the blood being 70 per cent. Iron and arsenic were given with plasmon and glucose, and on this there was some improvement. On July 20th a large glass tube was inserted into the abdomen, and from this serous fluid drained freely for two days. Her general condition, however, remained unsatisfactory, and she died on July 31st.

At the autopsy firm adhesions were found between the omentum and the abdominal wall, and there were old organised adhesions between the stomach and the diaphragm and between the liver, spleen, and diaphragm. The liver weighed 38 ozs., and was markedly cirrhotic, the lobules of liver substance being isolated by strands of connective tissue. The spleen was enlarged, deep red in colour, especially at the upper end, where there was a wedge-shaped patch deeply congested, resembling an infarct; in the centre of the congested area was a small abscess containing thick yellow pus, whilst two other small abscesses were seen in the substance of the spleen at the lower part. The heart was healthy, except that the mitral valve cusps were slightly thickened along the edges, and there was slight erosion of the edge of the posterior cusp. The capsule of the kidneys was somewhat adherent. The brain and other organs were healthy.

A microscopical examination of the liver (by Dr. Bertram Abrahams) showed great excess of interlobular connective tissue, with diminution of liver substance. In the connective tissue were numerous ducts, some lined with columnar and others with cubical epithelium, the latter predominating. The liver cells took the stain very badly, the protoplasm having a muddy appearance and their nuclei being very faintly coloured. There was some small round cell infiltration of the lobules but no fatty degeneration.

This case, in its clinical aspects, presented many difficulties in the way of diagnosis. There is no doubt that originally the patient was suffering from oligocythæmia and oligochromæmia. On her second admission, however, there was a further development, and suspicion pointed to lymphatic leucæmia. Her leucocytes were only 3,000 per cmm., and the ratio of white to red corpuscles was one in 493. The presence of finely granular basophile cells with the absence of non-granular cells was thought to be indicative of some pathological condition of the hæmatopoietic tissues. The essential change was apparently the presence throughout the body of large

numbers of small non-nucleated cells due to excessive proliferation. The anæmia was explained by the infiltration of the hæmatopoietic tissue of the bone marrow with a gradual diminution of the blood-forming area. The muscular substance of the heart had undergone a form of degeneration from the deposit of fine granules within the fibres. The alteration in the composition of the blood played an important part in the production of the oedema by increasing the permeability of the vessel walls. Such was the theory and it was probably incorrect, at all events it derived no support from the post-mortem appearances.

I have now, no doubt, a view that was entertained during the last few months of the patient's illness, that she was suffering from anæmia splenica with cirrhosis of the liver, that is from Banti's disease. It is to Professor Banti (14) of Florence to whom is due the credit of having first called attention to this peculiar malady. Its chief characteristics are:—(1) Anæmia, (2) enlargement of the spleen, (3) cirrhosis of the liver, and (4) ascites. It is not connected with malaria, syphilis or alcohol. All these conditions were present in this case. Banti regards the disease as a direct result of the splenic affection and not in the usual inverse sense of the splenic enlargement being due to the cirrhosis of the liver. It is, in fact, a hyper-splenomegaly. It is probably a toxæmia, the point of entrance of the poison being the intestines. In some cases the liver has been found free from cirrhotic changes. The disease is by no means common, but Senator (15) in a lecture recently delivered before the Medical Society of Berlin stated that in five years he had met with seven cases. He had investigated the condition of the blood in three cases and had collected records of seventeen other cases. Oligocythæmia was constant, and there was diminution of the hæmoglobin, but this was less characteristic, and bore no relation to the diminution in the number of the red blood corpuscles. The leucocytes were diminished in number, but to a variable extent. Banti recommended splenectomy, but the mortality from this operation is high. The advisability of resorting to it in this case was discussed soon after the patient was admitted for the third time, but the idea was negatived.

Case II.—A married woman, æt. 48, was admitted on October 7th, 1901, complaining of enlargement of the abdomen of four months' duration. She had suffered from morning vomiting for six months, the vomited matter often containing streaks of blood. The abdomen measured 42 ins. at the umbilicus and contained much fluid. The liver dulness could not be mapped out with any certainty. There was no definite alcoholic history, and there was no peripheral neuritis. It was thought that in all probability she had had syphilis. She had had seventeen children, of whom eleven were living. She had had various miscarriages at two, three, and seven months, and there was the scar of an ulcer over the left tibia, for which she had been treated in the hospital in 1897. She was placed on 5 grs. of iodide of potassium three times a day for a week, and then the dose was increased to 15 grs. three times a day for a fortnight, but from this she derived no benefit. Two days after admission paracentesis was performed, and 6 pints 15 ozs. of pale straw-coloured fluid were drawn off. After the tapping the abdomen at the umbilicus measured 36 ins., but the fluid speedily re-accumulated, and on the 29th the abdomen measured 42½ ins. On that day the patient having been placed under gas and ether an incision was made below the umbilicus, and 14½ pints of serous fluid were syphoned off, much more however escaping. The abdomen was explored with the finger, and the liver was found to be hypertrophic, hard, not very nodular, and covered with lymph. Mr. Spencer then made another incision in the median line about 2½ ins. in length, through which the omentum was brought and stitched with four kangaroo tendons to the abdominal wall. The stitches were removed on the twelfth day, and at the same time the large tube was withdrawn from the lower opening. The patient was able to get up on November 22nd, and on the 26th an examination showed that there was very little fluid in the abdomen, which measured 36 ins. She was dis-

charged on the 30th, a month and a day after the operation. She was readmitted December 24th with some increase in the amount of ascites.

This was a fairly good case for operation, but the conditions were not unexceptionable. For example, for the first few days after admission the temperature was 102°6' in the evening. The urine had a sp. gr. of 1030, and although usually free from albumin, sometimes a trace could be detected. She had a faint systolic apex murmur heard most plainly at the ensiform cartilage. Her arteries were not rigid, and another point in her favour was that she was cheerful and good-tempered.

Case III.—A married woman, *æt.* 50, was admitted to the hospital on November 20th, 1901, complaining of a heavy dull weight in the abdomen of three months duration. There was the usual indefinite history of alcoholism. She had had ascites and had been tapped ten days previously, seven pints of fluid being drawn off. There had evidently been some difficulty in closing the wound, and stitches had been inserted. There was a considerable quantity of free fluid in the abdomen and she measured 38 ins. at the umbilicus. The liver was not enlarged, and there was no increased area of splenic dulness. There was no valvular disease of the heart, although the first sound was feeble. The patient had a little general bronchitis, moist sounds being heard over both lungs. There was no albumin in the urine.

On November 28th, under gas and ether, Mr. Walter Spencer made the usual incision in the median line about two inches below the umbilicus and inserted a large glass drainage tube. He then made a second incision above the umbilicus and attached a portion of the omentum with kangaroo stitches to the anterior abdominal wall. On the following day the patient's temperature was 102°4', the pulse was 120, and the respirations were 44. The tube was removed on the fourth day, some of the stitches on the fifth day, and the remainder on the seventh day. The temperature remained over 100° for fourteen days, due, in all probability, to ether bronchitis. On the nineteenth day the patient was free from bronchitis, and on December 24th she was making rapid progress towards recovery.

This new departure in the treatment of cirrhosis of the liver naturally calls for some comment. The operation is generally known as the "Drummond-Morrison" operation, and there can be no doubt that this description should be retained. Dr. Drummond and Mr. Rutherford Morrison were the first to bring this mode of treatment into general use. It is true that Lens was the first to perform the operation, and much credit is due to him for his originality, but his paper was published in an obscure journal and in a language with which the majority of physicians are not acquainted, and he seems to have taken no steps to bring his discovery to the notice of his fellow-workers. The credit of a discovery rests not so much with its originator as with those who take the requisite steps to ensure its adoption. It is possible that Lens failed to realise the fact that he had inaugurated a new departure in the treatment of a hitherto incurable disease.

In connection with this operation it is of interest to consider what are the ordinary compensatory channels of circulation. It must be remembered that the obvious venous enlargement is but an indication of a more extensive and deep-seated effort of the same nature to relieve the congested portal system, and that on the extent to which this is developed depends to a very great extent the duration of the life of the patient. Some light is thrown on the subject by the study of a case of obliteration of the portal vein (pylphlebitis adhesiva) published by Osler (16). These anastomoses for convenience of reference may be tabulated as follows:—

PORTAL SYSTEM.

GENERAL SYSTEM.

1. The coronary veins of the stomach anastomose with the œsophageal, phrenic, and left renal veins.
2. The vasa brevia of the stomach anastomose with the left phrenic veins.
3. The gastro-epiploica of the stomach anastomose with the left renal veins.
4. The superior mesenteric veins anastomose with the left renal veins.

5. The hæmorrhoidal veins anastomose with the pudic veins.

6. Veins in liver adhesions anastomose with phrenic veins and veins in the abdominal wall.

7. The veins in the falciform ligament anastomose with the phrenic veins and veins in the abdominal wall.

All this has been carefully worked out by Sappey, and it is by way of the falciform ligament of the liver that we get the anastomoses which give rise to the enlargement of the veins of the superficial abdominal walls. Sappey's classification of the collateral channels is as follows:—

1. Anastomoses between the coronary veins of the stomach and the œsophageal plexus which discharges into the lower intercostal and azygos veins, and also communicates with the diaphragmatic vessels.

2. Veins passing in the coronary and suspensory ligaments of the liver and in the adhesions formed between the liver and the diaphragm.

3. The dilatation of a small vein in the round ligament affording free communication between the portal vein and the epigastric vessels.

4. Veins forming the system of Retzius which originating in the intestinal canal and anastomosing with the radicles of the portal vein, discharge into the inferior vena cava and its branches.

5. Communications between the superior and inferior hæmorrhoidal plexuses.

It is possible that a careful study of these cases may throw some light on certain undecided functions of the liver.

A point of more practical importance with reference to the success of the operation is the careful selection of the cases. We naturally reject those in which there is a suspicion of carcinoma, whether of the liver itself or of the peritoneum, or of the adjacent organs. When there is a history of syphilis the patient should be given full doses of iodide of potassium, with inunctions of calomel ointment, but should there be no improvement in the course of three weeks further postponement is inadvisable. The best results would probably be obtained in the pre-ascitic stage when the diagnosis rests on the alcoholic history with hæmatemesis and enlargement of the liver and spleen. Alcoholic subjects are notoriously bad subjects for operation, and it is not wise to wait until their tissues have undergone further degenerative changes. The earlier the operation the better the chances of a successful issue. An elevation of a temperature of three or four degrees in the evening is not to be taken as a ground for postponement, nor is the presence of a trace of albumin in the urine. Many of these patients, as shown by the published records have an apex systolic murmur, and in the majority of cases it may be safely disregarded. The risks of ventral hernia have to be taken into consideration, but they may be minimised by the application of a firm binder as soon as the patient gets up, but this is a comparatively small matter when issues of such grave importance are involved. In some patients the operation is inadmissible, and the following is a case in point:—

A woman, *æt.* 62, of German nationality, was admitted on September 21st, 1901, complaining of progressive weakness and enlargement of the abdomen of three months' duration. The abdominal walls were very tense from the presence of free fluid, and the area of liver dulness could not be ascertained. It was thought that in all probability it was an ordinary case of cirrhosis of the liver, though there was no alcoholic history. On October 22nd the patient was tapped and 9 pints 10 ozs. of fluid were drawn off. It was greenish in colour, had a sp. gr. 1020, was alkaline in reaction, and reduced Fehling's solution. The fluid speedily reaccumulated, and on November 10th it was decided to drain the abdominal cavity by the introduction of a large glass tube, and at the same time to ascertain definitely the condition of the viscera. Mr. Spencer, on introducing his finger, found thickening of the uterus and appendages, evidently malignant in origin, with secondary deposits in the liver, a discovery which precluded the performance of the Drummond-Morrison operation. There was no family history of carcinoma, and the

TABLE OF CASES OF THE DRUMMOND-MORRISON OPERATION.

No.	Under care of	Date of Operation.	Sex	Age	Condition of Patient.	Result.
1	Van der Meulen	1888	—	—	—	Died in a few hours of shock.
2	Schelky	1889	—	—	—	Died on 14th day of peritonitis
3	Th. Lens	June 6, 1891	M.	61	Atrophic cirrhosis with ascites	Died Nov. 24, 1891. P.M.
4	Drummond & Morrison	Sept. 3, 1894	Fe.	42	Liver smooth on surface and not enlarged. Ascites	Lived 19 months. Tapped 69 times. No P.M.
5	Drummond & Morrison	Oct. 22, 1895	Fe.	39	Liver cirrhotic with fatty degeneration	Lived 2 years and died after operation for ventral hernia. P.M.
6	Drummond & Morrison	Jan. 13, 1897	M.	42	Hepatic cirrhosis, enlargement of the spleen and ascites	Alive and well, Jan., 1899
7	Talma	—	M.	9	Enlargement of liver and spleen with ascites	A year later was alive and well and the spleen had decreased in size
8	Ewart & Hayward	Aug., 1897	Fe.	49	Calcification of adherent pericardium, chronic congestion of liver and ascites	Died a year later. P.M.
9	Neumann	Nov. 2, 1898	M.	45	Splenic tumour and ascites	No ascites six months after the operation
10	Weir & Lambert	Nov. 4, 1898	M.	43	Liver and spleen enlarged, and ascites	Died on the fifth day of peritonitis
11	Rolleston & Turner	July, 1899	M.	45	Spleen enlarged, but not the liver. Ascites	Alive and well six months later
12	Rolleston & Turner	July, 1899	M.	52	Alcoholic history and ascites	Five months later in bed with abdomen and oedema of the legs
13	Murrell & Spencer	Feb. 20, 1900	Fe.	20	Banti's disease, enlargement of the spleen, hepatic cirrhosis and ascites	Died July 31, 1901. P.M.
14	Frasier	July 25, 1900	M.	45	Alcoholic history. Enlargement of liver and spleen	Six months later alive and able to go out daily
15	Mansell Moullin	—	—	—	—	Died 1 week after from exhaustion
16	Mansell Moullin	—	—	—	—	Died 4 weeks after of pleurisy
17	Mansell Moullin	—	—	—	—	Discharged and lost sight of
18	Mansell Moullin	—	—	—	—	Alive and well 2 years after the operation
19	Mansell Moullin	—	—	—	—	Alive and well 2 years after the operation
20	Murrell & Spencer	Oct. 20, 1901	Fe.	48	Hypertrophic liver not very nodular	Able to get up Nov. 22, discharged on the 30th, readmitted Dec. 24 with some ascites
21	Bossowski	—	Fe.	9	Liver cirrhotic. Ascites	Ascites developed less rapidly after the operation
22	Murrell & Spencer	Nov. 28, 1901	Fe.	50	Liver but slightly nodular. Much ascites	Suffered from ether bronchitis, but on Dec. 24 doing well

patient had had no vaginal discharge, although it was subsequently ascertained that for some time she had suffered pain on defecation. She died from exhaustion on November 28th, and an autopsy was not considered necessary.

There are one or two other minor points to be considered. Should the operation be performed under a local anæsthetic? I think not. Frazier endeavoured to perform his operation under local anæsthesia, but after opening the peritoneal cavity the manipulation excited so much pain that it was necessary to give ether. Although in operations about the abdominal viscera most surgeons prefer chloroform on the ground that ether may fail to cause perfect relaxation, we have in our cases found gas and ether answer fairly well. Should stimulants be given after the operation? I see no objection to the adoption of this course. The second of my patients was allowed four ounces of port daily and it did her no harm. She realised for the first time what was meant by "compensation."

Paris Clinical Lecture.

CANCER OF THE HEAD OF THE PANCREAS.

By PROF. JACCOUD,

Physician to the Paris Hospitals.

[FROM OUR PARIS CORRESPONDENT.]

You may remember a patient whom we had in our wards some weeks ago. He was a mason by trade, who, on admission, presented some peculiar appearances to which I directed your attention as soon as I saw him, pointing out that they enabled us to arrive at an almost complete diagnosis, by simple inspection, without any physical examination of the patient. The diagnosis was subsequently confirmed by palpation, but this was not absolutely necessary. Two things, both very important, were noticeable. First, extreme emaciation, with profound marasmus, and, secondly, generalised jaundice of a greenish hue.

The icterus might lead one to believe that the hepatic organ was at fault, and that the emaciation

was due to some special malady of that gland, but the diagnosis was very easy and you would have committed a very great error in not thinking of cancer. There are cases of jaundice similar to the case in question, which are produced by affections other than cancer, but such pronounced emaciation as that of our patient could not be explained otherwise than by a cancer.

On the other hand the answer to the first question put to the patient relative to the duration of the malady was decisive; up to two months ago he felt well enough to continue his work. When we uncovered the patient we were struck with the tumefaction of the right hypochondrium; through the emaciated tissues all the details of the subjacent organs could be recognised with the greatest ease. We found an enormous liver forming a mass which filled the whole region. Associated with this mass could be felt an ovoid tumour, larger below than above, descending into the flank and following the movements of the diaphragm at the same time as the liver. The diagnosis was consequently that of a cancer of the liver, as far as inspection went. To go farther, palpation was necessary.

What was there yet to be known? We had to find out whether the gall-bladder was affected by the cancer, or whether it was only the bile duct that was obstructed. On account of the generalised jaundice it was necessary to examine the condition of the pancreas, as well as that of the stomach, because the cancer of the liver might conceivably be secondary to an epithelioma of the stomach. All these organs had to be passed in review in order to arrive at a complete diagnosis.

In the light of ordinary clinical experience, and in view of the condition of the patient, it was sufficient to say that it was a case of cancer, but from a scientific point of view, it was necessary to examine in detail all the elements of diagnosis which I have enumerated to you.

To that end we proceeded to palpate the patient, and palpation revealed that the walls of the gall-bladder were not thickened, nor did they present any irregularities, it was distended with fluid, but did not participate in the cancerous growth. There was no reason to incriminate the stomach, for no carcinoma could be felt.

In the pancreas matters were different. On gentle manipulation it was possible to pass the hand under the liver up to a spot where we distinctly felt a hard tumour, which could be nothing else than the head of the pancreas. This fact had an important bearing on the diagnosis. If the liver were affected it was only secondarily, either that it contained a few cancerous nodules, or that the cause of the condition was analogous to that of the gall-bladder; the latter was filled with bile; the liver might be also simply engorged. Such was the opinion at which I arrived. For two months it was engorged with liquid, because the excretory ducts for the bile were closed.

The head of the pancreas is, we have seen, the seat of a cancerous growth. Not a drop of bile passes, and the jaundice is complete. The urine is loaded with normal and abnormal pigments. The fæces resemble putty. The presence of fat in the fæces is said to be a sign of the destruction of the pancreas; it is not necessarily so, but in our case it existed.

During the sojourn of the patient in the ward nothing particular happened, death taking place by the progress of the marasmus.

Before giving you the details of the autopsy, I wish to avail myself of the opportunity of drawing your attention to an interesting peculiarity presented by this patient.

In the inguinal region we found large indurated lymphatic glands. These, when associated with other

signs are of great importance in the diagnosis of abdominal cancer. For some years, considerable value was attributed, and rightly so, to the glands at the root of the neck, while the inguinal glands were overlooked, that is an error to which I never fail to call attention each time the opportunity presents itself. In many cases, the significance of the glands in the neck has the importance placed upon it, but less, however, than that of the glands in the inguinal region for, I, who was the first to draw attention to the latter, have always noticed the existence of these enlarged glands when the supra-clavicular ganglions were also enlarged, though the latter were more recent. I have never seen the supra-clavicular glands enlarged without the inguinal glands being also affected; while, on the other hand, I have frequently found the inguinal glands enlarged without the clavicular glands following suit. The clavicular glands are enlarged whether the case is one of abdominal cancer or of pulmonary tuberculosis. Consequently the possibility of tuberculosis must be eliminated before entertaining the idea of cancer.

Just a few words in respect of the autopsy. The liver was large, but not cancerous. The gall-bladder was greatly distended. The head of the pancreas was hard, dense, and adherent to the duodenum. An enlarged gland was adherent to the hilus of the liver, and another cancerous gland was fixed to the head of the pancreas. The hepatic ducts were greatly dilated. All the other organs were healthy.

THE NECESSITY OF MAKING PROVISION FOR THE CARE OF THE CONSUMPTIVE POOR.

By B. H. STEEDE, M.D.,

Resident Physician, National Hospital for Consumption,
Newcastle, co. Wicklow.

THE startling novelty of the view brought forward by Professor Koch at the late British Congress on Tuberculosis on the subject of bovine-tuberculosis has obscured what seems to me to have been the main argument of his address. He noticed how other pestilences—plague, leprosy, cholera—have been successfully encountered, and the question he proposed was, whether the energy that is now being spent in combating tuberculosis, is being properly directed. Is it directed at the root of the evil so that tuberculosis must sooner or later die out, or is it partially wasted on measures which, however beneficial to individuals, can only have a slight effect in reducing the annual mortality from phthisis? And the answer he gives, is, that although much is being done, yet that the most important measure of all has been scarcely attempted, namely: the isolation of necessitous consumptives unsuitable for sanatorium treatment.

His aim is the extermination of tuberculosis, and he does not despair of this being ultimately accomplished, but one absolutely necessary means to this end must be the care of that class of consumptives which, more than all others, contributes to the renewal and dissemination of the disease.

Dr. Koch warns us that too much must not be expected from sanatoria. He regards as an indisputable fact that consumption in its early stage is curable, and he even assumes that, if sanatoria are reserved strictly for early cases, as many as 50 per cent. of those treated may be cured, still "the total effect must be but moderate." The great mass of consumptives—viz., advanced cases—are left untouched, and will for ever cause the disease to flourish no matter how many sanatoria for early cases may be established. Sanatoria, unaided by

other measures will never "get to the root of the evil so that sooner or later it must die out."

The primary aim of sanatoria is the cure of consumption, and as a means to this end their position is secure and unrivalled. It is fairly safe to predict that so long as we have consumptives among us so long shall we have sanatoria. They will always be supported because of the direct benefits they confer on the patients treated. And, as regards the prevention of consumption, they are a great help, partly by the cures effected and the isolation for the time of other cases, but chiefly by the knowledge they spread of the nature of the disease, the measures necessary to avoid infection, and the best mode of treatment. So far so good, but in any attempt to eradicate consumption the cases unsuitable for sanatorium treatment must be considered. Some of them, owing to their circumstances or habits, spread infection much more than others. These should be lodged in special institutions and their houses disinfected.

Homes for the incurable consumptive poor are the most pressing necessity in dealing with the mortality from tuberculosis. The need of such institutions has, of course, been felt ever since the infectious nature of consumption was established, but latterly not only their desirability, but their practicability, is being more and more recognised. Dr. Koch recommended the same measures at the Berlin Congress in 1899, and quite recently, in addressing the German Central Committee for the establishment of sanatoria, Professor Fraenkel, of Berlin, also powerfully advocated the isolation, as far as possible, of consumptives. This, he was convinced, would bring them one step nearer the attainment of their high aim—"Deutschland ohne Tuberculose."

Dr. Ring, a delegate from the Michigan State Government to the Tuberculosis Congress, read a paper on observations he had made as to the family history of 242 cases of phthisis. The particulars he gave tended to show that the fact of parents being phthisical tended to confer immunity from, rather than predisposition to, phthisis in the offspring. His observations are at least some evidence of how unsettled is this question of the exact influence of heredity in phthisis. The public are generally convinced that the disease "runs in the family." Whether this may be so to a slight extent, is of little practical importance. If they could get into their heads that it is a disease which is liable to attack successive inmates of the same house rather than successive members of the same family they would not only have a much truer notion of the real state of things, but also a knowledge that would greatly further measures necessary to protect them from infection.

Eleven years ago Cornet published the results of an elaborate series of researches he had made proving the presence of tubercle bacilli in the dust of rooms inhabited by consumptives.

Dr. Coates, of Manchester, has lately most carefully carried out a similar investigation. His methods and the results he obtained, which are very interesting and important, are fully described in a paper read by him at the Congress. He examined the dust taken from three classes of houses:—

1. Dirty houses inhabited by consumptives who took no precaution with regard to disposal of sputum, &c.

2. Apparently clean, well-kept houses, but which were inhabited by consumptives who took no proper precautions.

3. Very dirty houses, but which were known *not* to have been inhabited by consumptives for at least several years.

He found tubercle bacilli in most of the houses of the first class, in half of the houses of the second class, but in no houses of the third class. If one

individual is attacked by tuberculosis no trouble or cost incurred in the attempt to save his life may be thought too great, yet we are careless about the disinfection of a house, though we know if left uncleansed it is likely to bring the disease to many future inmates. It is in the overcrowded dwellings of the poor that the chief necessity for preventive measures exists. From these dwellings we want—in as many instances as possible—to remove the consumptive and to cleanse and disinfect the house. When this is not possible we want, by giving instruction and help, to do the best we can for the consumptive in his own home and to lessen the chance of his infecting others. Hence the value of notification, not necessarily of every case of tuberculosis, but of those cases which are obviously in danger to the community. Voluntary notification has been at work for some time in Brighton, Manchester, and Liverpool; it is now being tried in several other English towns. How it has worked in Manchester was fully described by Alderman McDougall. In one year over 2,300 cases were notified, and over 2,300 houses disinfected. In New York voluntary has been superseded by compulsory notification. Since the beginning of the year compulsory notification has also been enforced in Norway. At the final meeting of the Congress a resolution moved by Dr. Niven, of Manchester, was adopted, urging the desirability of notification "in all districts where efficient sanitary administration renders it possible to adopt the consequential measures."

In France a great deal is being done by means of "Anti-Tuberculous Dispensaries." The first of these was established by Dr. Bennett Léon so recently as January, 1900, and the results attained proved so practically useful that they led some months later to the founding of "The General Association of Anti-Tuberculous Dispensaries for the Prevention and Cure of Pulmonary Tuberculosis." Such dispensaries have now been established in several large French cities. They endeavour to do the best that can be done in their homes for all those tuberculous patients whose necessary cessation from work would otherwise condemn them to utter distress. In every country the consumptive poor must necessarily receive help in some form or other from the community. These dispensaries systematise, direct, and increase help given by private or public benevolence. They see that the danger from infection is minimised, and provide nourishment and material aid as funds permit. They can often so improve his immediate surroundings as to give great benefit to the patient and much protection to his friends. Judging from the reports given to the Congress the working of these dispensaries in France seems to have been an unqualified success. Dr. Calmette described them very fully. He believes they should precede and complete the foundation of sanatoria. "Precede," so as to find out suitable cases for sanatorium treatment, and "complete" this treatment by watching and helping discharged patients, thus endeavouring to meet the great difficulty which encounters every sanatorium for the poor. He concludes his paper thus:—

"We do not think that we shall cure many patients by just giving them the means of feeding and living under better conditions, but among those who come to us some can easily be cured; a little rest and good living will enable them to resist the disease. These will be sent to the public sanatoria when such exist. The other patients, the most numerous, alas! those who understand the gravity of their illness when it is too late to stop its course, those who can find no room in the hospitals, and who, encumbered with a family, try to earn their bread until they fall down worn out and dying, these will be taken under the protection of the dispensary

which will assist them according to their necessities. It will furnish them with the means of livelihood without endangering their surroundings, without sowing infection and misery around them." He believes that it is not only the duty but the interest of society to multiply works which have such aims in view. Dr. Bennett Léon, who was one of the first to establish such dispensaries, is still more emphatic. He says: "The future of France, and that of other nations, who are absolutely defenceless against tuberculosis, is dependent on the success of these dispensaries for the prevention of tuberculosis."

A discussion at the Tuberculosis Congress on Sanatoria, opened by Dr. Clifford Albutt, showed how universally the value of this means of treating consumptives is now recognised. Sanatoria are regarded as a necessity. There is now no question as to whether they should be supported, but only *how* they should be supported and their number increased. If, however, the only object of sanatoria were the cure of individual cases the term of treatment should be much longer than is usually the case. Dr. Clifford Albutt thought that to bring about a real cure two winters and one summer would probably be required, and to attain what the Germans describe as an "Economic cure" six months' treatment would be probably necessary in the majority of cases.

At this discussion Dr. Philip gave particulars of some cases in which evident improvement only began after several weeks' treatment, and then steadily continued. Many comparatively advanced cases do well, but only if the treatment is long continued. Sir Herman Weber knew a patient with temperature ranging from 98.5 to 103° for three years fully recover at last. Dr. Weber also made the interesting statement that out of twenty-five cured cases known to him eighteen had developed distinct gout. He, with many others, believes that there is some antagonism between gout and tuberculosis.

Our results at Newcastle are, I believe, at least fully equal to the average results obtained in Continental popular sanatoria. From the German official statistics it is seen that four-fifths of those treated "either died or were totally unfit for work" three and a-half or four years after discharge. Owing to the absence of compulsory insurance it is more difficult for us to follow the after-history of our patients, but so far, as well as we can learn, the results seem to be more promising.

Whether alcohol, except in very small quantities, is, in itself, good, bad, or indifferent in the treatment of consumption is still unsettled. Formerly it was more generally believed to be good; now it is generally considered bad. There is, however, no question but that indirectly it is the cause of a vast amount of consumption by its influence on the social conditions of the poor, and by the multitudinous ways in which the frequenter of the public-house is exposed to tuberculous infection.

Consumption, bad housing, and intemperance act and re-act on each other. Any measures that lessen any one of these three evils must tend to lessen the two remaining.

The Mortality in Foreign Cities.

The following are the latest official returns, and represent the last weekly death-rate per 1,000 of several of the populations:—Calcutta 35, Bombay 50, Madras 58, Paris 20, Brussels 16, Amsterdam 13, Copenhagen 15, Stockholm 16, St. Petersburg 24, Moscow 22, Hamburg 16, Munich 22, Vienna 18, Prague 23, Trieste 28, Rome 15, Venice 23, Cairo 34, Alexandria 34, New York (including Brooklyn) 18, Philadelphia 17.

NOTES ON A CASE OF CHORIO-EPITHELIOMA WITH PULMONARY METASTASES. (a)

By CUTHBERT LOCKYER, M.D., F.R.C.S.,

Physician to Out-patients, Samaritan Free Hospital for Women, &c., &c.

In this case the evidence of an abortion lay in the fact that the patient lost blood freely four months before admission, the loss continuing until the case was sent to hospital; whether a period had been missed prior to the onset of the hæmorrhage was not ascertained.

The patient was æt. 42. She had given birth to seven children. The last confinement took place three and a-half years before admission into the Samaritan Hospital. Three abortions were recorded, the last being thirteen years before the patient was sent to the above hospital.

The patient was admitted with evident uterine enlargement, and in a condition which prohibited operative interference. The uterus was perforated by a new growth in its walls, and secondary deposits were found in the lungs.

The main features revealed in section of the primary growth Dr. Lockyer summed up as follows:—

1. The uterine mucosa ceases to be distinctly recognisable where the growth begins, that covering the muscle in the neighbourhood of the growth (*i.e.*, at the internal os) being infiltrated and degenerate.

2. The muscularis is deeply invaded by a small-celled infiltration, and venous channels contain cellular emboli at a considerable distance from the growth.

3. The muscularis is invaded by protoplasmic masses, in which no differentiation of individual cells is possible, and also by large cells of various shapes and sizes containing either a single large granular nucleus or two or more smaller nuclei.

4. The individual muscular bundles are widely separated, the intervals being sometimes filled by the above cellular elements or by leucocytes, but in other cases being empty, having been probably filled originally by oedematous fluid.

5. Large hæmorrhagic areas occur in the muscularis, these areas having no endothelial lining, and lying apparently free between the widely-separated muscle fibres.

6. The muscle cells are in every stage of atrophy and degeneration; their nuclei are swollen and granular, but for the most part maintain their spindle-shape; their protoplasm in some cases stains badly, or refuses to stain at all.

7. The walls of the uterine arteries are thickened, their lumina (as also those of the veins) are filled with thrombi in which an undue proportion of white cells are seen deeply stained with hæmatoxyline—appearances suggesting the presence of acute inflammation of the muscle tissue, coupled with degeneration.

The sections of the growth itself show that it is largely made up of necrotic tissue and remains of hæmorrhage, but the growth becomes more cellular and protoplasmic in its deeper part where it is attached to the uterine muscle; here columns of protoplasm are seen spreading out among the hæmorrhages as solid bands in which polymorphic nuclei are sometimes visible. In other cases within this area the protoplasm occurs in plates from which proceed columns of various shapes and sizes. The former are vacuolated and

(a) Abstract of paper read before the Obstetrical Society of London Jan. 1st, 1902. For discussion see page 29.

contain nuclei similar to those in the columns, but less regularly distributed.

There is no line of demarcation between the growth and the uterine muscle, the above trophoblastic columns run in between the muscle fibres, as do also the free hæmorrhages and large epithelioid cells, so that in the superficial muscular layers there is an intermingling of the above elements with degenerate swollen muscle fibres.

Deeper in the muscularis the growth is succeeded by a dense round-celled infiltration, and deeper still are seen large mononuclear cells within venous channels, on their way to form metastases. No true representation of chorionic villi were demonstrated, but syncytial masses formed the main feature of the primary growth, and the same were found in the pulmonary metastases. Dr. Lockyer pointed out that under the collective designation of deciduoma malignum at least two varieties of tumour histologically distinct are distinguishable.

1. Syncytioma derived from the outer layer of the chorionic villus.

2. Tumours containing no syncytium, but which are made up of large modified connective tissue cells bearing a close resemblance to the decidual cells of the maternal portion of the placenta.

A lantern demonstration showing the structural differences between these two types of growth followed the reading of the paper.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, JANUARY 1ST, 1902.

The President, Dr. PETER HORROCKS, in the Chair.

PNEUMOCOCCIC MENINGITIS SIMULATING PUERPERAL ECLAMPSIA.

DR. THOMAS WILSON (Birmingham) read a short paper on this subject. The patient, æt. 35, had had seven children; on admission to hospital she was comatose, with great pallor and cold extremities; the temperature was 100·8°. Shortly after admission the pallor gave way to cyanosis, the coma deepened, and the patient died within an hour and a half. Some urine was drawn off shortly before death, and showed the presence of a slight amount of albumin, and 1·5 per cent. of sugar. Inquiry into the history of the patient revealed no evidence of previous kidney trouble; her present pregnancy had proceeded as far as the sixth month, and had been quite healthy till five days before admission, when she began to be very ill, and suffered from headaches. On the fourth day of her illness fits supervened, and her medical attendant, who found albumin in the urine, diagnosed eclampsia. The fits were succeeded by unconsciousness, in which state she was brought into the hospital. The post-mortem examination showed that the kidneys were healthy, as were the uterus and ovum. The chief pathological condition found was a septic meningitis; this involved the whole surface of the brain, which was smaller than the normal, and was covered by creamy pus. The upper lobes of the lungs were oedematous, the lower lobes oedematous and congested, but there was no pericarditis, pleurisy, pneumonia, or peritonitis. There were no signs of tuberculosis, nor of middle-ear disease; a cultivation of the pus on the meninges revealed a micro-organism of the nature of a diplococcus, which resembled both in its appearance and in its reactions Frankel's pneumococcus. Dr. Wilson briefly discussed the case from the point of view of diagnosis, remarking that it was practically impossible to distinguish it from a case of eclampsia. He dwelt on the importance of a complete post-mortem examination in every fatal case of convulsions and coma during pregnancy. He also noted the presence of sugar in the urine, taking the view that the sugar was derived by re absorption from the mammary glands.

The PRESIDENT endorsed the observations of Dr.

Wilson on the importance of making a careful and thorough post mortem in these cases.

Dr. AMAND ROUTH said that it was important to remember the lesson taught by the paper, that convulsions might be due to other causes than eclampsia. With regard to the presence of sugar in the urine, he was not convinced that the sugar originated in the mammary glands, especially in view of the experiments of a recent observer who amputated the breasts of pregnant ewes, and yet found sugar in the urine. It was possible that the liver was the source of the sugar.

Dr. HERBERT SPENCER mentioned a case in which he operated for pyosalpinx, in which there was a large quantity of pus. The patient did well till the tenth day, when the odour of her breath gave rise to a suspicion of sugar in the urine. This turned out to be the case. The patient shortly afterwards died with paralytic symptoms. Sir William Gowers attributed the death to septic meningitis, involving one cerebral hemisphere. The parallel of Dr. Wilson's case suggested that the sugar in the urine might be related to the cerebral septic condition.

CARCINOMA OF THE BODY OF THE UTERUS.

Dr. A. H. N. LEWES showed two specimens of this condition, removed by abdominal panhysterectomy; and discussed the relative advantages of the abdominal and the vaginal operation in these cases.

Dr. F. J. McCANN raised the question whether the tubes and ovaries ought not to be removed in every case of cancer of the body of the uterus; he had seen two cases of recurrence of the disease in the tubes when these had been left behind.

Dr. AMAND ROUTH spoke favourably of the combined vaginal and abdominal operation; the preliminary steps carried out by the vagina considerably shortened and facilitated the abdominal part of the procedure. With regard to Dr. McCann's remarks, it seemed to him that the way of dealing with the tube would depend on the situation of the uterine growth; if this did not involve the cornua the tubes could be left, but when the whole fundus was involved they ought to be removed.

After some remarks by Dr. Spencer and the President Dr. LEWES replied.

Dr. CUTHBERT LOCKYER read notes of a case of

CHORIO-EPITHELIOMA WITH PULMONARY METASTASES, which will be found in another column under the heading of "Original Communications."

The PRESIDENT, after complimenting Dr. Lockyer on his excellent paper and demonstration, said that he leaned to the view that the malignant growth in these cases was of foetal origin; he considered that this view was supported by those cases in which chorio-epithelioma followed on hydatidiform degeneration of the chorion.

Dr. HERBERT SPENCER recalled a previous discussion on Deciduoma Malignum at the Society, in the course of which the late Dr. Kanthack expressed the view that these growths should be classed as sarcomata. He would not himself express an opinion, but he agreed with Dr. Lockyer that there were probably two kinds of case, namely, one in which syncytial growths were present, and another in which the tumour appeared to be of decidual origin. For the present he considered it convenient to retain the term deciduoma malignum to include both varieties.

Dr. LOCKYER replied.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, DEC. 19TH, 1901.

The President, Mr. EDGAR A. BROWNE, in the Chair.

CASES.

MR. BICKERTON showed a patient with melanotic sarcoma of the conjunctiva.

Mr. ROBERT JONES related (1) five cases of fracture of the fifth metatarsal bone due to direct violence. Although no reference to this fracture was found in the text-books he thought that the lesion was common. Radiographs of each case were shown, and the fracture was found to be almost at the identical spot in each

case, just below the base of the fifth metatarsal bone. The injury in each case was due to the body weight acting upon the foot when in the position of equino varus, and was evidently due to a cross breaking strain, the bone yielding close to the very strong ligaments which bind the metatarsal base to its surroundings. The symptoms of the fracture are pain over the site, a little swelling, no crepitus, and pain on attempting to invert the foot. (2) A series of cases of coxa vara, illustrating the bi-lateral infantile type, and contrasting it with the changes in the neck usually present in extreme rickets. He also showed the adolescent type, which in one instance was very extreme, the rounded head being enlarged, its lowest portion reaching three-quarters of an inch below the acetabulum. The skiagram distinctly explained the very marked limitation in movement, which gave the patient great pain. It presented a very rare appearance. The head of each femur was opposite the acetabulum, and the neck formed an acute angle to the shaft. The trochanters were not thickened. Three and a-half inches from the top of the trochanter the lower border of the femoral head on the left side was within a quarter of an inch from the shaft. Part of the rounded head was excurved out of the acetabulum towards the femoral shaft. The neck was irregular and somewhat narrowed in contact with the head. The upper border of the left neck measured three and a-half inches, the lower three-quarters of an inch. On the right side the head practically touched the shaft four and a-half inches from the top of the trochanter. The superior border of the neck was four and a-half inches in length, the lower one and a-quarter. The same kind of irregularity was noted, and the neck was very thinned towards the femoral head. The head seemed also to be levered out of the joint. The ætiology and treatment were discussed.

THE SPEEDY RELIEF OF PILES.

Dr. WM. CARTER read a note on a speedy method of relieving the pain of piles. A suddenly protruded pile which caused extreme pain, the intensity of which was not diminished by a prolonged external use of several much-praised remedies, was almost immediately and permanently relieved by a single application of 10 c.c. of cocaine and 20 c.c. of menthol in oil of theobroma. These were made into a cone which was rubbed over the part.

Dr. A. BURNS GEMMEL read a paper entitled

ANÆSTHETIST AND OPERATOR,

in which he stated that charges had been made against those engaged in the administration of anæsthetics of "want of knowledge and want of care," and that surgeons at the same time object to anæsthetists claiming to be "supreme in their own place," and maintain that the surgeon should be master over the management of the anæsthetic as over every other detail of the operation. Medical men engaged in the administration of anæsthetics were divided into (1) those under direction and bound to obey orders, such as the medical student and house surgeon, and (2) those who, recognising the great responsibility of the work, undertake it, and therefore ought not to be interfered with in any way in the performance of their duty. The duties of anæsthetist and operator were briefly considered, and it was evident that each ought to give his whole attention to his own work. In the event of a fatality each for his own work is accountable to (1) his conscience, (2) the relatives and friends, (3) the coroner and jury. Friends and relatives know that the surgeon comes to operate, and in the event of disaster from the anæsthetic will blame the anæsthetist. Young surgeons do not administer to the extent they did before the special anæsthetist came into existence, and the older surgeons have ceased to administer. Seeing numerous cases merely as an operator does not give experience of anæsthesia, and therefore the surgeon, old or young, has no right to dictate to the administrator. The special anæsthetist is only available for hospital patients, and the richer portion of the community, consequently the greater part of this work is undertaken by the general practitioner, who fully recognises his responsibility, and any attempt to deprive him of this

responsibility and lay it on the operator would tend to make him less careful, and therefore less skilful. Dr. Burns Gemmel is always ready to do whatever the operator wishes if it can be done with safety, but strongly objects to the assumption of the right to "dictate" by the operator. He who does the work must bear the responsibility, and he who bears the responsibility must be allowed to do his work without interference.

Dr. H. BRIGGS said the reader of the paper might have saved himself a great deal of trouble by pointing out who was to be supreme authority, or "captain of the ship" if not the operating surgeon.

Dr. WM. ALEXANDER said that in the coroner's court the responsibility for the anæsthetic is distinctly thrown upon the operating surgeon. The patient selects his surgeon, leaves himself in his hands, and looks upon the anæsthetist as an assistant to the operator. In cases where the family doctor administers he has to bear the brunt of the disagreeable things said or thought by the relatives, and so interposes between them and the surgeon, but even then the case is considered by them as a fatality in the practice of the operator. As a general rule the preliminary arrangements for the administration are agreed upon between the surgeon and anæsthetist, but if there be any difference of opinion, the surgeon should carry the day. In the present day, patients often think more of the danger of the anæsthetic than of the operation, and if this fear continues, probably it may arrive at such a pitch that the patient will select his favourite anæsthetist first, and leave him to call in the surgeon as the junior. Until that occurs, the surgeon should lead the way. The surgeon would incur a grave responsibility if he asked the anæsthetist to give more anæsthetic when the latter declared it would be dangerous to give more. In all cases anæsthetist and surgeon should stand shoulder to shoulder, bearing the responsibility together, and standing up for each other.

Mr. F. T. PAUL thought the responsibility in regard to all preparatory treatment must generally rest between the practitioner and surgeon. The choice of the anæsthetic in certain cases must lie with the surgeon. Responsibility in fatal cases would vary with the circumstances. When the death was entirely due to the anæsthetic, the anæsthetist was entirely responsible; when entirely due to the operation, the surgeon; but in Liverpool it was customary to hold the surgeon responsible to the public. Practically, friction between the surgeon and the anæsthetist was unknown in Liverpool, and very little give and take would render any such contingency impossible.

Dr. F. W. BAILEY was convinced that operator and administrator must work together, dependently and not independently; they must co-operate. In cases of doubt or gravity in the course of the administration, we court an opinion, and none is better able to give it than the operating surgeon. Operator and anæsthetist were likened to a tandem team, each doing his share of the work, dependently and to the best of his ability.

Sir W. M. BANKS said that after hearing the paper he was only the more strongly confirmed in the view that in the conducting of an operation there must be some one person in supreme command, and that person must be the surgeon. The surgeon's position was compared to that of a general: a defeat is associated with the name of the general, however much it might have been caused by the fault of a subordinate. In the case of a death from an anæsthetic, it was the surgeon who had to bear the brunt of the odium, because his name was generally more widely known to the public than that of the anæsthetist. As regards legal responsibility, the Liverpool coroner had stated that he regarded the surgeon as answerable for all that occurred during the progress of an operation. With reference to the preliminary arrangements, it was important to note that the surgeon had almost invariably seen the patient before the operation, and necessarily knew something about his position; while the anæsthetist (unless the medical attendant) saw him for the first time. If a patient during an operation were dying of hæmorrhage the anæsthetist might logically say that that was none of his business, but, if the

patient was dying, say from some vomited matter sticking in his larynx, dare the surgeon say he was not concerned with that, and refuse to do a tracheotomy? Were an equal dual control established difficulties of a very serious character might occur. So far maintaining these opinions as he had always done, he had never on any occasion had any difference of opinion with the anaesthetist, but he felt certain that but for his supervision he would not have seen two deaths out of some eleven or twelve thousand cases, but more likely twenty. So far from producing harmony at an operation, Dr. Burns Gemmel's views would tend to produce discord and a sense of mutual distrust between operator and anaesthetist. But after all the whole discussion was purely an academical one.

Drs. and Messrs. Damar Harrison, G. G. Hamilton, T. R. Bradshaw, G. Newbolt, A. Grunbaum, Nathan Raw, and W. Bark also spoke, and Dr. BURNS GEMMEL replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DEC. 19TH, 1901.

The following specimens were exhibited:—

Mr. R. FAVELL: Series of Uterine-Fibro myomata (b); Diseases of Fallopian Tubes (b); Parovarian Cyst (b).

Dr. T. H. MORTON: Blood Cysts from Uterus (b), Tubal Ectopic Gestation (b); Intestine strangulated by band (b); Intestine strangulated by loop (b).

Mr. E. J. PYE SMITH: Pyloric Stomach excised for malignant disease (a) and (b).

Mr. E. J. SCORAH: Sarcoma of Small Intestine (a); Carcinoma of small intestine (a); Cirrhotic Kidneys (b).

Mr. S. SNELL: Encapsuled Sarcoma of Orbit (a) and (b); Epithelioma of Cornea (b); Tubercle of Iris (a); Endothelioma of orbit (a); Sarcoma of Choroid recurring in orbit—(i) Section of eyeball; (ii) Growth from orbit; (iii) Bony walls of orbit exfoliated after chloride of zinc; (iv) Microscopical series of tumours. A large collection (about 70) of mounted sections of eyes.

Dr. WILKINSON: Hydatid of lower end of femur (b).

Dr. ARTHUR HALL: Typhoid Ulcers (b); Mucous casts Intestine (b); Brain—thrombotic softening (b); Aortic aneurism (b); Heart—fatty degeneration (a); Liver—acute yellow atrophy (a); Kidney—fatty degeneration (a); Heart—amyloid degeneration (a).

a = Microscopic; b = Macroscopic.

There was also a demonstration of specimens, illustrating various features of tuberculosis, by Drs. J. Robertson, M. Hector, and Arthur Hall. These included—

Cultures of *B. tuberculosis*, streptothrix and actinomyces.

Microscopical specimens of tuberculosis of cow's udder, horse's lung, guinea pig's glands, various human organs, lupus nodules, urine, &c.

Specimens illustrating experimental tuberculosis in animals.

A large collection of specimens, illustrating tuberculosis of different organs, both human and animal.

France.

[FROM OUR OWN CORRESPONDENTS.]

PARIS, January 5th, 1902.

CAUTERISING THE EYEBALL.

M. VALLIN read a paper at the Académie de Médecine on the substitution of cauterising the eyeball to enucleation in children. He said that enucleation of the ocular globe in children was a deplorable operation on account of the deformity which results, and which becomes more exaggerated as years advance. Except in the case of malignant tumours, recourse should be had to the method recommended by M. Dianoux, and which consisted in practising on the cornea, without, however, opening the anterior chamber, a cauterisation in the form of a star with the point of a thermocautery

maintained at a low red heat. That done, a circle is traced around the centre of the cornea, and the disc thus circumscribed is pierced quickly in the centre with the point of the thermocautery brought to a white heat so as to allow the aqueous humour to escape.

The wound is then powdered with bismuth, and a compressive bandage applied during three days. At the end of that time the bandage is removed and the parts washed with boiled water and a solution of cocaine and eserine instilled between the lids each day until the wound has cicatrised. After all irritation has disappeared massage is practised a few days and finally the cornea is tattooed.

In all the cases treated by this method the results were very satisfactory.

TREATMENT OF PERICARDITIS.

In treating the subject of pericarditis, M. Deguy said that the first application to be made was that of revulsives, and more especially that of wet cupping, which had the advantage of diminishing the inflammation. The actual cautery was certainly efficacious against the pain, but as a revulsive it was inferior to the wet cupping. Its application at the end of the affection was, however, good treatment. Local refrigeration has also its advantages; it may be temporary or permanent. When the former is employed, ether spray is the best agent, but permanent refrigeration is best obtained with the ice-bag, over the heart, a piece of flannel intervening. Gendrin attributed to the treatment the decrease of the local pain and anguish as well as the tumultuous palpitations of the heart.

When the revulsion is not needed to be so intensive, tincture of iodine, or the following liniment employed by Prof. Huchard may be utilised:—

Juniper spirit, 3iv;
Lavender spirit, 3ij;
Ess. of turpentine, 3ij;
Tincture of benzoin, 3ij.

If the pericarditis was of rheumatismal nature frictions with an ointment of salicylate of methyl might be tried, or the following much recommended by M. Bourget, of Lausanne:—

Salicylic acid, } 3iv;
Ess. of turpentine, }
Lanoline, } 3iij.
Axungia, }

As to blistering, he would not recommend it on account of the risks it exposed the patient to by its action on the renal epithelium.

Besides revulsion which acts on the pericardium and calms the local pain, it is necessary to act on the heart by stimulating the contractility of the cardiac muscle and raising the arterial tension. Digitalis is naturally the agent of choice; it may be given in pill form as follows:—

Digitalis (powdered leaves) }
Calomel } aa i gr.
Squill extract }

Four daily during three days, then two during three days more.

M. Deguy is in the habit of following up the effects of the digitalis by continuing for some days pills of sparteine.

Sulphate of sparteine } j grain.
Ext. of convallaria }

For one pill. Two daily.

In order to lessen the chances of effusion into the pericardium, diuretics are recommended, the most important of which is theo-bromine. It is best administered with benzoate of lithine thus:—

Theobromine viij gr.
Benzoate of lithine ij gr.

For one wafer. Two to three daily.

PRECAUTIONS AGAINST DIPHTHERIA.

The Paris Health Committee has just published a new list of precautions against diphtheria. These require that the sick person shall be immediately isolated, that those who attend him shall wear a special antiseptically treated overall, which must never leave the sick chamber, that no food shall be partaken of in the sick chamber, and that persons attending the patient must wash their hands and faces with a disinfectant, and if suffering from any open scratch on the face or hands, must cover it with a coating of collodion before approaching the patient. There are also stringent regulations for the disinfection of the room. The municipal authorities must see that these rules are obeyed, where necessary must take over the charge of the patient, and, in the case of the poor, find lodging for the patients' relatives while the house is disinfected. Special stress is laid on these regulations, as during the last few weeks diphtheria has again been very prevalent in Paris.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 4th, 1902.

THE PRESENT POSITION OF THE CONFLICT AGAINST PUERPERAL FEVER.

DR. PAUL SCHENK, of Berlin, has an article in the *Vierteljahrssch f. Offentl Gesundheitspf* on this subject. Our present position is one mainly of avoidance. In regulations for prevention one of the first is the limitation of internal examination and obstetric operations. At every internal examination and operation the greatest cleanliness of the hands and instruments is called for, as well as of the external genitals and the parts adjacent to them. Especially as regards disinfection of the hands, the method is not of so much importance as the thoroughness of the cleansing. Prophylactic vaginal injections are useless, and must be forbidden. Midwives must be put into a position to master antiseptic details, so that temporary cessation from practice may be unnecessary. To attain this object it is necessary that the education and methodical training should be of a higher order and that a sufficient minimal income be assured them, so that the apprehension of old age and sickness may be removed from them. Along with midwives there should also be a large number of suitable assistants, who have undergone some training, so that the midwife herself may be relieved from continuous personal attendance on her sick charge. By close attendance to regulations, the mortality of childbed outside of institutions should be reduced at least one-half.

At the Medical Society, Hr. Westenhöffer showed a preparation of

FROTHY LIVER IN A CASE OF SEPSIS AFTER ABORTION. The preparation was taken from a patient from the Charité. She was a woman, æt. 22, who had an abortion on November 7th. On the 10th she had a rigor, and died on the 17th. Examination showed a mushroom-shaped os, the cervical canal admitting a finger, the uterus was the size of the fist, with offensive placental remains. Autopsy eleven hours after death. In the lungs, the enlarged pultaceous spleen, and the kidneys were abscesses varying in size from a millet seed to a cherry. The uterus was the size of the fetal head, the mucous surface covered with diphtheritic exudation, and in the cervical canal was a fibrino-purulent deposit. On section numerous thrombosed vessels were seen, the thrombi having broken down, and a similar condition in the parametrium, the ovaries being acutely inflamed. On taking out the liver a crackling was felt as in emphysema of the skin. Under the capsule were numerous greyish blebs, filled with gas. Section through the liver left numerous frothy vesicles on the cut surface. Out of the portal branches, and out of cavities, hollows and spaces came numerous gas vesicles mixed with bloody fluid; the gas was colourless and devoid of odour.

Cultivations taken from the cut surfaces immediately after section gave in pure cultivation thick rods of the size of anthrax bacilli with rounded corners, which coloured well with aniline especially by Gram's method. These bacteria were found in numerous other sections, especially in the branches of the portal vein, in the liver capillaries also, but in much less numbers and not so regularly. The cells were driven apart and showed larger spaces between them than in the normal. No injury to the body of the cell could be detected, and especially there was no necrosis. Scarcely any bacteria were seen in the parenchyma of the liver forming the walls of the gas vesicles, the gas was therefore not formed on the spot but in the beginnings of the capillaries and branches of the portal vein, and thence driven to the spot where external pressure was the least, i.e., in the softened liver tissue. Two guinea-pigs inoculated therewith died in twelve hours with diffuse peritonitis with clear watery exudation and gas formation in which bacteria could be demonstrated, whilst an inoculated rabbit remained healthy. The port of entry of the bacteria, in the speaker's opinion, was not the uterus, but the metastatic abscesses in the lungs. The liver contained no trace of sugar. The speaker then related an observation of Bernhardt of the case of an idiot, æt. 44, who died in fifteen hours of acute sepsis. At the autopsy eight hours after death thick anthrax-like bacilli were found, which were not cultivated further. They stained readily and were apparently identical with those of the case just reported. The points of entry were the bile passages and the portal vein. In America a mixed infection was assumed with the bact. emphysematocum as in the case of a woman in the Johns Hopkins University Hospital whose body became swelled out by gas to twice its size during life.

Hr. Stadilmann mentioned a case in his own wards of purpura hæmorrhagica. There was hæmorrhage from the skin, nose, and vagina, with fever. Death from anemia and cardiac weakness. The case impressed him as one of sepsis. The person was a virgin. A wound was detected on the finger. Testing for bacteria gave

staphylo- and streptococci. Immediately after the patient's death a sample of the blood from the heart was taken, and this in addition to the cocci mentioned revealed a micro-organism completely identical with that shown by the previous speaker. In that case also there was frothy liver and formation of gas in the various organs. He cultivated the organism and made experiments with it. He obtained a good deal of carbonic acid and an inflammable gas, probably marsh gas, and nitrogen. The gas was formed from carbohydrates. When sugar was added to a bouillon a large quantity of gas was formed in these acids. When the acids were weakened by neutralisation the formation still went on, but to a lesser extent. The cultivations were not carried to a complete conclusion, but it was interesting, as the bact. emphysematosum was cultivated almost during life, and the gas was collected and examined.

Hr. Senator mentioned several cases of septicæmic joints in which gas was present. One was the case of a French soldier in 1870 with diseased knee-joint; there were two others with gas in the shoulder-joint. In both cases the gas was carefully removed and once the bact. coli was found. Biermer was the first who showed the possibility of pneumothorax arising from within without any external injury.

Hr. Wastenhoeffer observed that in nearly all recorded cases there was some external wound.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Jan. 4th, 1902.

CORTICAL INNERVATION OF THE RECTAL SPHINCTER.

At the "Gesellschaft" for Internal Medicine, Hockwart and Fröhlich gave an account of their experiments on dogs to determine the cortical innervation of the sphincters. Bechierew and his school found that irritation of the cortex about the gyratus sigmoideus behind the fissure of the cruciata produced contraction of the sphincter ani. The constricting fibres are supposed to pass through the nervi erigentes, as cutting of the erigentes produced paralysis of the sphincters. This relaxation of the sphincters was observed by both Valentin and Gowers in the act of defæcation in the human subject.

Frankel and Fröhlich, in experimenting on dogs, pointed out that the inhibitor of the sphincters was conveyed through the ischiadicus; if, however, these fibres could be removed the constrictions were found to be reflex, as centripetal stimuli caused the sphincters to open. Hockwart and Fröhlich now come forward with experimental facts to prove that the sphincters have a cortical relationship, as relaxation of the sphincter was produced by a particular area, while constriction can be produced in the same vicinity.

HYDROCEPHALUS CHRONICUS.

Buchsbaum produced a chronic hydrocephalus, with hernia in both orbital regions. From the history and course of the disease he noted that the patient was eighteen months old and was the tenth child. The mother having aborted three times, gave birth to one dead child, while other four children died within the first year; one, aged seven years, now lives, and is perfectly healthy from the description given. From birth

the child exhibited had a large head, with small fontanelles, and up to the seventh month remained quite stationary; but about this time it took suddenly ill one night with high fever and fits. Next month the head was observed to increase till it reached forty-six centimetres in the thirteenth month (18 inches); at the present time it measures 53 centimetres (20.7 inches) in circumference, giving the head the form of a pyramid with the chin as its apex. The bones of the head were soft and elastic, and could be easily compressed. The fontanelles were wide and gaping, extending down the sutures to the base of the cranium, the bones of the forehead being the only ones in union. The veins were large over frontal, nasal, and temporal bones. Both bulbi, more particularly the right, were turned outwards by round elastic swellings, which had forced their way through the cranium.

In the fundus of the right eye was a crescentic area of atrophy. All the other organs of sense appeared to be intact. There are still tonic contractions in the muscles of the extremities of the throat. Mannaberg observed that he could find no pulsation in the tumours. Hochsinger remarked that these cases pointed to an antiluetic therapy, and according to his own experience the present case was one of heredity luetic hydrocephalus. Konigstein was of opinion from numerous observations of protrusive bulbi that the cause was due to a turning forward of the inner orbital wall which, owing to the thinness of the bone allowed an easy communication with the orbit and brain.

MYIOSIS INTESTINALIS.

Freund reported a case of dermatomyositis on the crown of the head of a child, æt. 9, which was recognised as impetiginosa eczema. This was observed under a dirty brown scab covering an abscess in which were found the larvæ of the sarcophila Wohlfarti, a parasite which he believed had never been observed in Vienna before.

Pollak recorded a case of myiosis which he had attended privately till death. For several months before the demise bloody stools were often passed. The question at the post-mortem was whether these parasites were the original cause of the bowel lesion or if the bowel lesion preceded the settling lair of the larvæ. Professor Lichtmann gave it as his opinion that the parasite was the original cause.

Csokar demonstrated a quantity of material showing the effects of myiosis in animals. The common parasite in the animal canal was the obligate while that of the human bowel was the facultative parasite. He pointed out three forms of myiosis, viz., cutaneous, nasopharyngeal and intestinal. The two former were not so common in man as the latter. Myiosis intestinalis appears in animals most frequently among the horse tribe and is usually of the muscaridea order such as the gastrophilus and the oestrus. Oestrus equinus or gadfly swarms in the months of July and August, laying their eggs in the long hair of the animal. The horse in scratching itself, or licking its coat takes the ova into the mouth, where they begin to develop into larvæ, and, reaching the mucous membrane of the stomach, get entangled in the rugæ of the mucous membrane, where they may lie the whole winter, as they can obtain

nourishment from the fluid contents of the organ. In the month of March the ripe maggot is thrown off with the excrement, and shortly after passes through a chrysalis stage before reaching the mature state. He considers paedogenesis to be impossible, that is, the young fly generating in the canal. During their retention in the alimentary tract a slight catarrh is induced, often leaving behind hard cicatrices with polypoid enlargements. He had only five cases of personal experience in human myiasis, and these belong to the luster fly homalomyia, of which there are two species, the scalaris and canicularis. One of the cases was due to the blue-bottle or sarcophaga carnaria. This insect is a vivipar, but has no paedogenesis, although a coprophagite living on excrement for its subsistence. According to Brauer the entomologist in his distinction between obligate and facultative parasites in flies maintains that the human race is only afflicted by the facultatives. Observers in Russia and Freund in Vienna have found sarcophilic and meigenii epidemic, more particularly in syphilitic patients. The common blue fly (calliphora) is allured by sarcoid, while sarcophaga is not. True oestridæ have never been observed in man.

The Operating Theatres.

FRENCH HOSPITAL AND DISPENSARY.

OPERATION FOR SUPPURATING CYST OF BROAD LIGAMENT.—Mr. O'CALLAGHAN operated on a woman, æt. 35, who had been admitted with a tumour in her left side. During the previous three months she had had several attacks of severe pain, with high temperature, and was rapidly losing flesh. As her condition was becoming serious she was sent in from the out-patient department by Dr. Dardenne. On admission, a distinct swelling on the left side was palpable, but on examination it was found to be fixed, this having been evidently caused by the previous attacks of local peritonitis. The evening temperature was 102°. Operation was therefore deemed necessary. An incision was made in the median line below the umbilicus for about two inches; on opening the peritoneum the intestines were found to be adherent all over the anterior part of the cyst; after separating these (during which there was considerable oozing), the operator, after enlarging the abdominal wound, endeavoured to enucleate the tumour whole, but unfortunately it burst and flooded the peritoneum with offensive pus; this necessitated thorough flushing of the pelvic cavity with water at a temperature of 110° until the liquid returned clear, the portion of the abdomen above the wound being shut off by flat sponges which had been placed *in situ* before any attempts at enucleation had been made; this precaution, Mr. O'Callaghan pointed out, prevents pus or discharge from finding its way all over the peritoneal cavity. The edges of the cyst wall were next attached to the abdominal incision at its lower angle; a glass drain was inserted and the original incision closed. Mr. O'Callaghan said that owing to the previous repeated attacks of local inflammation it would have been unwise to persevere in enucleating the whole cyst wall, as the adhesions were so fixed and of such old standing. He remarked that he had not been at all surprised at the bursting of the cyst, as the walls were quite friable and came away in pieces. Such a condition of things was

nowadays, he considered, fortunately rare, as these cases generally came to operation, having been diagnosed at an early period before any local peritonitis has occurred, when it is comparatively easy for the surgeon to enucleate the cyst from the broad ligament. He also considered that a case in the stage in which he found the one he had just operated upon was as difficult as any abdominal operator would care to meet.

The patient's temperature became normal at once after operation, and she was sent to the French Hospital convalescent home at Brighton four weeks afterwards.

OPERATION FOR PELVIC ABSCESS.—The same surgeon operated on a very fat woman, æt. 30, who was suffering from a large pelvic abscess. The diagnosis of the exact condition was difficult owing to the large depth of fat on her abdomen. She had had acute pain for a week before admission, with an evening temperature of 102°, and very quick pulse (about 112); a distinct swelling about the size of a cocoanut was easily felt bimanually on the left side of the abdomen; though it was very hard, fluctuation in it was distinct. As it was impossible to get at it through the vagina it was decided to open the abdomen. An incision was therefore made in the middle line through three inches of fat to get to the muscular layer, underneath this there was another inch of adipose tissue, and when the peritoneum was opened there was still a big, fatty omentum to get through which was adherent over the top of the abscess. Large flat sponges were then packed round the seat of the abscess, and the operator tried to stitch up the sac to the abdominal incision before opening it, but it burst whilst the adherent omentum was being separated. After thoroughly swabbing out the broad ligament and cleaning up the rest of pelvis, the wound in the abdomen was closed with great difficulty owing to the depth of the cavity, this being caused by the thickness of the fatty parietes, it being found impossible to bring the abscess wall up to the incision; in order to drain extra-peritoneally, a gauze drain into the abscess sac was brought out in the lower corner of the abdominal wound. Mr. O'Callaghan said that the operation was rendered much more difficult by the extent of the fat in the abdominal parietes. He remarked on the danger of such a collection of pus in the pelvis of a woman suffering from such an enormous excess of adipose tissue, and as her heart was evidently, from the pulse, in the same condition, if the abscess had burst previously to operation the result certainly would have been fatal, especially as the pus evacuated was most foetid.

Four weeks after operation the patient was convalescent, although she had been threatened several times with heart failure, which, however, had fortunately responded to hypodermic injections of 1·50 gr. of sulphate of strychnine.

The Doctor and the Burglar.

DR. OLDERSHAW, of Liscard, Cornwall, was the hero of an exciting episode the other evening. His suspicions having been excited, he proceeded to a careful search of the premises, which resulted in his finding a tramp lying beneath his invalid wife's bed. As he resisted arrest, Dr. Oldershaw fired at him, and the would-be burglar was struck in the thigh by a ball which fractured the femur, whereupon he became more amenable to persuasion, and he was ultimately conveyed to prison.

BANTI'S DISEASE AND ITS TREATMENT.

ELSEWHERE in the columns of the present issue of *THE MEDICAL PRESS AND CIRCULAR* will be found a valuable contribution by Dr. Murrell on the subject of Banti's disease. That particular form of cirrhosis of the liver is attended by a well-marked group of concomitant signs and symptoms, and was first described by Professor Guido Banti, of Florence, in the year 1882. The peculiar associated features he described are enlargement of the spleen and the liver, together with profound anæmia. The malady is usually known as splenic anæmia, and is identical with the "spléno-mégale primitive" of French authors, and with splenic cachexia, splenic leukæmia, and lymphadenoma splenicum. It has hitherto attracted little attention in this country, but several cases have been published in France, and in 1891 Bruhl published a collection of fourteen cases from various sources. In a paper read before the Medical Society of Berlin Senator stated that in five years he had seen seven cases. The condition of the spleen is regarded by some observers as primary, with a resulting cachexia arising from interference with that organ. Sometimes there is persistent elevation of temperature. Not infrequently symptoms resembling those of hæmophilia are present, recurrent hæmorrhages from the stomach and bowels, often to an alarming extent, being the most common manifestation. It is noteworthy that many of the patients do not furnish the objective signs of severe anæmia, although the red blood corpuscles are diminished in number. The most characteristic thing in the physical condition likely to attract attention is the ascites due to the secondary cirrhosis of the liver. The disease is not caused by malaria, syphilis, or alcohol. It may obviously be due to a blood parasite, but so far no organism of that nature has been

discovered. Indeed, the ultimate cause of the trouble has yet to be found, for apparently no satisfactory explanation has been yet forthcoming as to the essential pathological factor in the splenic enlargement, which is in itself probably symptomatic. With regard to diagnosis it has to be distinguished from splenic leukæmia, from pernicious anæmia, from the cachexia of malignant diseases and from other forms of splenic enlargement. It is most commonly confounded with cirrhosis of the liver, as may be readily imagined from the foregoing description of the cardinal facts of the disease. Indeed, there appears to be some ground for the belief that the malady, although usually regarded as one of extreme rarity, is in reality common enough. Now that the attention of medical men in the United Kingdom has been drawn to the matter it will doubtless be studied forthwith in the thorough and scientific manner that so happily characterises modern medical research among our countrymen. They may, perhaps be stimulated to a more than ordinary amount of exertion upon recognising the curable nature of a certain percentage of cases. The prognosis is usually bad both with regard to the duration of life and the prospect of recovery. It is true that now and then the disease may run a chronic course, but, apart from surgical interference, the ultimate outlook is more or less hopeless. It is that very point which renders Dr. Murrell's article of practical value to everyone concerned in the treatment of disease. There can be little doubt that a competent knowledge of Banti's disease would enable medical practitioners to save a certain number of otherwise hopeless cases. Splenectomy has not met with sufficient success to justify its adoption, but the anastomosing Drummond-Morrison operation is of a most hopeful nature, and possibly its results may be as favourable as they have proved in some cases of cirrhosis of the liver. Under anti-septic precautions there is little danger attending the procedure, which may be described briefly as follows:—An incision is made in the median line about two inches below the umbilicus, and a large glass tube is inserted, whereby the ascitic fluid may be drained away. Another incision is then made above the umbilicus, and through this opening the liver, spleen, and adjacent organs are examined by the finger. If there be no malignant disease a portion of the omentum is attached to the anterior abdominal wall and in that way a collateral circulation is established. In some cases, either at the first or at a subsequent operation, it is desirable to scratch the surface of the liver and spleen so as to afford additional channels of communication between the portal and systemic circulation. The accumulation of fluid in the abdominal cavity is prevented or at all events retarded, and the patient's life prolonged. Dr. Murrell has published the first cases of Banti's disease treated in the United Kingdom by the Drummond-Morrison operation, and he may be congratulated upon the able monograph which lays the matter before the medical profession in this country.

ANÆSTHETIC MORTALITY.

A CORRESPONDENT, who deplures what he does not hesitate to describe as the avoidable waste of life occasioned by the unskilled administration of anæsthetics, forwards for publication a table of the deaths recorded in the lay Press day by day. It is evident that these figures represent part only of the total mortality. His statistics show that during the first year of the new century no less than ninety-eight deaths occurred under anæsthetics. Of this number sixty-five were males and thirty-three were females. Twenty deaths occurred in private practice, and seventy-eight in hospitals and dispensaries. The mortality under particular anæsthetics is shown in the following table:—

	Males.	Females.	Total deaths.
From Chloroform	46	22	68
„ Mixtures	6	3	9
„ Ether	5	4	9
„ Gas and Ether	1	1	2
„ Ether followed by Chloroform	2	—	2
Kind of anæsthetic not stated	5	3	8
Total	65	33	98

One noteworthy feature of the evidence given at the inquests is the apparent inability to explain the precise cause of death in each instance, the witnesses in the majority of instances merely admitting their ignorance, falling back on one or other of the stereotyped formulæ—fatty heart, shock, and the like—without any anatomical proof to support the hypothesis. Another circumstance of considerable importance is the curious absence of exact information as to the mode of administration and the quantity of the drug used. Even more remarkable is the smallness of the amount alleged to have been used when, by chance, this detail was touched upon—quantities often so small as virtually to render it impossible that death could almost have been due to the anæsthetic. In not a single case was it suggested by the medical witnesses or the coroner that the fatal result may have been due to overdose, even when the symptoms—cyanosis, struggling, &c.—strongly pointed to asphyxia as the immediate determining cause of vital extinction. The mask and the drop-bottle were responsible for most of the deaths occurring under chloroform, but no importance has ever been attached to this detail, which is, nevertheless, profoundly significant. The remarkable preponderance of deaths under chloroform is, no doubt, due in large part to the fact that this anæsthetic is particularly affected by those whom, without disrespect, we may call amateur anæsthetists—that is to say, practitioners who are comparatively rarely called upon to induce anæsthesia. In conjunction with this fact we must also bear in mind that almost alone among anæsthetics chloroform is usually administered without the aid of any sort of apparatus, by a happy-go-lucky method of pouring an uncertain quantity of the drug on to a towel or mask, leaving it to the patient to give warning of danger by the manifestation of unequivocal symptoms of intoxication. The gravity

of the problem raised by these figures is even more obvious when we compare the present rate of mortality with that of years gone by. Our correspondent has taken the trouble to collect the returns of inquests in cases of death from anæsthetics for some years past, and although the value of his statistics is to some extent impaired by the fact that greater publicity is probably given to these catastrophes now than formerly, the brutal fact remains that whereas in 1888 the total number of inquests was only eleven, the number has gone on increasing annually to 46 in 1891, 60 in 1894, 83 in 1899, and, finally, 98 in 1901. It is quite possible, though no data are available to establish the fact, that the proportion of deaths under anæsthetics is not greater now than formerly. Even if this be admitted for the sake of argument, we fail to see that it provides any valid reason for acquiescing in so large a sacrifice of life as inevitable, seeing that experience shows unquestionably that the risk to life is directly proportionate to the skill and experience of the anæsthetist, and, in less skilled hands, to the employment of a proper inhaler. The inexperienced are precisely those who habitually have recourse to the most dangerous, because the least scientific, method of administration. The day will come, no doubt, when the public will awaken to the desirability of enquiring more closely into this question, and if reform is not forthcoming from within the profession, it may be forced upon it from without.

ALCOHOL FOR MEDICINAL PURPOSES.

MOST members of the medical profession recognise that under many circumstances brandy and whiskey are most valuable medicinal agents, which exert a definite therapeutical action, and for which an adequate substitute of a non-alcoholic nature cannot be obtained. Like many other names, however, the terms whiskey and brandy, by which, as a rule, the public understand certain well-defined products, have many attributes in the trade. The name whiskey, for instance, is now applied to many products of distillation which are wanting in the therapeutic and physiological properties which in the past secured for the liquid a place in the physician's list of trustworthy remedies. To secure this medicinal agent, malt or rye pot-still whiskey must be obtained. Grain, corn, molasses, and patent-still spirit should not be accepted. Patent-still whiskey has nothing of the therapeutic properties the physician looks for when he prescribes whiskey. Time in no way modifies the spirit; it comes over as an hydroxylate of ethyl and dissolved in water, and is the same years after the distillation as when quite fresh from the still. This spirit has little if any of the physiological effects of an old matured malt pot-still whiskey. It is wanting in the power of dilating the arterioles, which so diminishes the strain on the heart and allows of the internal viscera being unloaded. Its use is followed by the increased cerebral tension that manifests itself so often in violent hea

aches and the dreadful bursting sensation in the head with which drinkers of cheap whiskies are so familiar. Neither does it unload the liver nor kidney, and organic changes in these organs and catarrh of the stomach quickly follow its use. For these reasons we consider patent-still whiskey and blended whiskies containing patent-still whiskey as quite unsuited for therapeutical use. The disadvantages of raw corn, Indian corn, wheat, and molasses whiskies are well known, and it is unnecessary for us to dwell on them. We may, however, say that fresh whiskey of pot-still make is a maddening liquor, and quite unfit for use, we think no such spirit should be used until it has been matured for at least five years in wood. The necessity for this is evident when we recognise that in the distillation of malted barley by the old pot-still process the hydroxylate of ethyl comes over with a slight percentage of the hydroxylate of propionic and amylic alcohols; these alcohols, especially the latter, give the fine pineapple flavour of old Irish pot-still whiskey wares, and to the same, the well known physiological action of the spirit is due. But the acquiring of this flavour and property is a matter of time, the amylic alcohol ($C_5H_{11}O$) must be changed into amylic ether, or the oxide of amyl, together with a certain percentage of aldehydes. Until these changes occur both whiskey and brandy are unsuited for medicinal use; experience has taught that they occur more quickly in wood than in glass, they can be readily detected by their characteristic bouquet. To imitate this bouquet many flavouring agents are used, the majority of which consist of the so-called fruit wines and essences with added artificial ethers; but these do little but mask the patent-still and other cheap spirits—they never properly blend with the menstruum, and really convert the inferior spirit into a toxic agent. For medicinal purposes we consider that a pure pot-still whiskey—unblended—of fully five years in bond is most suitable, and is doubtless as efficacious as high quality brandy. It therefore constitutes an agent which can be prescribed by the medical profession with confidence.

Notes on Current Topics.

The Improvement of Nursing Schools.

It is to be hoped that in the course of time nursing may become a liberal profession. To attain that end there should be made certain improvements in the methods of educating nurses. Cabot has recently made this matter the subject of a very excellent paper in the *Boston Medical and Surgical Journal*. He thinks that, in the first place, nurses should pay for their training, and be taught by paid instructors. This would undoubtedly tend to bring into the profession a better educated class of women, and would put the students in a position to demand a thorough course of instruction. Nursing should be taught by nurses, medicine by physicians. Nurses should be prepared for private nursing by practice in families outside a hospital, and by the teaching of

nurses in active practice. It is urged, moreover, that the nurse's training should not be too exclusively technical, but should include some liberal studies such as sociology, history, and literature. She needs to study subjects which tend to give a deeper and truer sympathy with human nature, and also to prevent her from getting warped and depressed by the weight of concentrated sorrow and suffering which her life forces upon her notice. The educated nurse has resources to turn to when her work is done, and can carry with her into her work a consciousness of other and more normal sides of life, which will give her balance and enthusiasm in the thick of her difficulties. There is much in Cabot's remarks, but we have doubts as to the practical application of his ideas. It is, however, certain that many nurses are imperfectly taught, and this is in large measure due to the placing in power of matrons who are wholly unfitted for their post. We question, too, whether the nurses in some of our large hospitals get sufficient recreation, and the authorities often seem to forget that the preponderance of work which makes Jack a dull boy may be equally responsible for making Jill a dull girl.

Acute Myocarditis.

THE association of acute myocarditis, with endocarditis and pericarditis, can certainly not be said to have been overlooked, yet that it possesses great importance when it exists has not yet been sufficiently widely recognised. It is not suggested that acute inflammation *commonly* extends deeply into the muscle from the inflamed serous membranes, but when it does so how may extensive involvement be recognised, and with what other conditions may it be confounded? In a short but suggestive paper by Dr. Alfred Stengel in the *Journal of the American Medical Association*, of December 14th, the points on which greatest stress is laid are a marked rapid pseudo-hypertrophy of the heart, with a weak pulse of low tension, and the "slapping, irritable impulse." But the character of the sounds of the heart are also of importance. They are, perhaps, best described as conveying the impression of being produced at an abnormal distance. When this character is noticed associated with a markedly increased area of cardiac dullness, the diagnosis of pericardial effusion may be erroneously made. In a case which came under notice some years ago, the patient was found to be extremely ill with a high temperature and delirium. His illness had commenced suddenly with rigors. He had had an ill-defined rash which led his medical attendant to advise his removal to a fever hospital. It was then found that his area of cardiac dullness was very greatly increased, no impulse could be seen or felt, his pulse was frequent, small, and compressible, the cardiac sounds were indistinct and "distant." No bulging could be made out on the front of the chest. No murmur or friction sound could be determined. The diagnosis of pericarditis was made, and at the post-mortem such was found, but without effusion,

ulcerative endocarditis with myocarditis also existed. There is a danger that students may become so absorbed by the so-called more scientific methods of diagnosis that careful, intelligent "feeling the pulse" may cease to be practised. Many students and young practitioners "feel the pulse" principally because they know that most patients expect them to do so, and it is done while the watch is held in the other hand. It is called "feeling the pulse," but it too often is nothing more than "counting" it. The student should be made to understand that to intelligently feel the pulse is to perform a highly scientific exercise which requires the very highest degree of skill. He should be taught to train himself on numbers of patients with comparatively normal pulses, so that he may be able to recognise marked abnormality. Definite terms should be taught which describe definite physical conditions. Such terms as "shaky," "weak," "rapid" (when "frequent" is intended), &c., should not be allowed. Teachers sometimes delight to describe the pulse in expressive terms; many of them are undoubtedly such, but they may convey very different ideas to students to what were originally intended. A just estimation of the character of the pulse will be found of the greatest value in the effort to form an opinion of the amount to which the myocardium is affected in cases of acute inflammation of the serous membrane of the heart.

Medical Inspection of the Refugee Camps.

It has been officially announced that the whole of the Refugee Camps, thirteen in number, within the Orange River Colony, have been placed under the supervision of an experienced English Medical Officer of Health. The camps are such merely in name, being more like huge hospitals than the organisations usually associated by the public with that term. To maintain five to six thousand soldiers, all in the prime of life, in good health in camp is no easy matter. Many agencies combine to baffle the efforts of military hygienists in the control of camps. We need only refer to the outbreak of diarrhoea among the troops of one of the Divisions of the German Army taking part in the annual manoeuvres this year. These troops, all in the healthiest age, under the charge of skilled army doctors, operating at home, in peace, and within reach of easy means of preventing and checking disease, were so prostrate with diarrhoea that the whole manoeuvres had to be stopped. In South Africa the "camps" consist of all ages and sexes, with supplies which are necessarily limited, owing to the exertions of the relatives of the Refugees themselves, who are busily engaged wrecking trains and preventing transport. The difficulties of the sanitary management of the camps are, therefore, enormous, and quite unparalleled. Never before has any Government had to provide everything for a large population like this, in a dozen localities, for so long and in such a climate. We do not hesitate to say that there has been considerable lack of discretion

in the well-meant efforts made. The general management is entirely under a military officer, with necessarily no medical knowledge, and who is practically despotic. The medical officers of the camps have often had to be taken without selection, many being Boers, who had been merely village doctors, some only retired from fighting against us. The Civil Superintendents of the camps, too, have not all been men of knowledge or experience. How could they be? Yet they can hamper the doctors greatly. Of course the present appointment, though an admirable step, cannot of itself be of any use, unless loyally supported.

Hepatotomy.

THE simplicity of the surgical procedure in many cases for the removal of biliary calculi and the very high degree of success it has met with, has resulted in its being now almost daily performed. Yet the difficulties sometimes met with have proved extremely embarrassing even to operators of the greatest skill and experience. Ideal procedures cannot always be carried out in practice. It is perhaps in the discovery and adoption of means of relief that even greater genius may be shown than in the proposal of "radical" methods. Dr. W. E. B. Davis, in an address before the "American Association of Obstetricians and Gynaecologists" at Cleveland, U.S.A., records several cases in which hepatotomy was performed with a considerable degree of success. It is admitted that the field for hepatotomy in gall-stone diseases is very restricted, yet it is asserted that it may offer "much assistance in bridging the patient over till in better condition for a radical operation." The part of the operation to which the name is given consists in incising the liver in the hope that the bile may drain from the divided bile ducts. The incision is packed with gauze to control bleeding, and the gauze is then brought out through the wound in the abdominal wall. Dr. Davis' views are formed as the result of experiments on dogs as well as from the effects produced on patients on whom it was inadvisable or impossible at the time to perform a more radical operation. It would be interesting to determine where this incision would be best made, probably the immediate neighbourhood of the incision in the abdominal wall would be the part generally selected, but if an incision in some other part should be found more likely to be generally useful the advisability of making a second parietal incision elsewhere might be considered.

"Pick-Me-Ups."

THE practice of taking what are popularly known as "pick-me-ups" is unquestionably as widespread as it is pernicious. We do not allude to alcoholic nips, indulgence in which comes under the head of chronic inebriety, but to the various draughts dispensed on a large scale by retail chemists to persons who, at some hour of the day, experience the necessity of reinforcing their jaded energies. An instructive article on this subject appeared in a recent

number of the *Daily Mail* from the pen of Mr. Sidney Thompson, who is evidently possessed of considerable knowledge of this phase of human weakness. A large number of people are apparently dependent on cocaine, and, curiously enough, among them is, so chemists affirm, a tolerably large proportion of medical men. The drug is taken by injection or by insufflation. It is to be feared that the habit is gradually spreading among the public. Of a less actively injurious sort are the draughts of tonic biters, the need for which afflicts many men about town during the forenoon, gentian, strychnine or nuxvomica in an acid or alkaline medium being the usual ingredients. Mr. Thompson credits the introduction of tabloid products with the spread of the habit of self-medication, and no doubt there is some truth in his assertion in view of the ease with which these ready-made medicines can be obtained without the trouble of producing a prescription. People who depend upon pick-me-ups are usually impervious to argument, their excuse being that they feel, as Mr. Thompson puts it, "beastly limp." It is well, nevertheless, to direct attention to the fallacious and ultimately disastrous nature of such stimulation, if only to divest the victims of the habit of the excuse of ignorance.

Professional Advertisement in High and in Low Places.

SOME day or other the General Medical Council will be called upon by an indignant profession to define the term advertisement. So far it has been determined that the systematic touting for patients in connection with medical aid societies is "infamous conduct" in a technical sense, deserving of the heavy penalty of expulsion from the *Register*. But what is to be done with those high up in the profession who lose no opportunity of bringing themselves before the public in the discussion of matters that do not absolutely demand a purely personal treatment? As regards the modern treatment of tuberculosis, for example, there is no theory and no special knowledge that could not be given to the world just as well without as with the signed name of its intelligent author. Yet the profession is daily confronted with the spectacle of a little knot of medical baronets, knights and physicians—not to mention their offspring—airing their views with untiring persistence in public prints and on public platforms, both in season and out of season. Only last week a well-known enterprising baronet accorded a long interview to a newspaper reporter, and it is not easy to see how that action differs materially from the offence of the medical aid society promoters. Needless to say, the gentleman in question is a Fellow of the Royal College of Physicians, London, whose strict code of paper ethics appears to be drawn up with a view of silencing outside rivals in the professional race. Certainly, with such a state of things going on naked and unabashed in the face of day, it will be impossible for the General Medical Council, or any other medical organisation, to find fault with

Jones, Brown, or Robinson, who rush into public print fired with the spirit and the example of their leaders.

Death Certificates and Unqualified Practitioners.

ONE of the few obstacles, direct or indirect, that lie in the pathway of the unqualified medical practitioner is his difficulty in furnishing death certificates. Time was when great laxity prevailed in that direction, but of recent years it was fondly imagined that the local registrars of deaths throughout the United Kingdom had sternly set their faces against irregular certificates of death. From time to time, however, circumstances come to light that show there is still room for improvement in the attitude of these officials with regard to documents of the kind in question signed by unqualified persons. A week ago, for instance, in the course of a coroner's inquest held in Westminster, it transpired that the local registrar accepted a certificate of death from an unqualified medical practitioner. There could be no oversight, as the document was not tendered on the official form. In this instance the registrar was a law stationer, residing in New Inn. It is to be hoped that the matter will be raised in the Commons on the opening of Parliament, with a view of revising the conditions of tenure of the local registrarships, and also of rendering it absolutely impossible for a death to be registered on the evidence of any but a legally qualified medical man or a coroner. The Registrar-General has offered valuable help hitherto by his instructions to his district officers, but his hands apparently require strengthening by legislative instructions. The action of the unqualified practitioner in attendance upon the deceased woman who formed the subject of the inquest is in the safe keeping of Dr. Bateman, the able Secretary of the Medical Defence Union.

Bovine and Human Tuberculosis.

SHORTLY after Koch propounded his theory of the incommunicability of tuberculosis between man and animals, New York City took steps to put it to the test. Four calves over ten weeks old were fed and injected with diseased human sputum. Subsequent tuberculin tests gave doubtful reactions. One calf killed disclosed no lesions or bacilli. The other calves are now apparently healthy, but will complete a year's observation, followed by autopsies. The experiment is made officially by the Health Board, and, it is said, "will settle local opinion upon this subject." If experiments upon four calves will settle such a subject as this to the satisfaction of the authorities in New York, then they are very easily satisfied. Prolonged and serious experiment alone can be productive of any decided results. Had the calves shown signs of tuberculosis from the method employed, it would have gone some way (but not far) to prove the fallacy of Koch's theory. But that they remain healthy at present proves nothing. There are so many fallacies that

might creep in to make the experiments untrustworthy, and we should not care to accept as decisive results obtained from such meagre experimentation.

Tinctorial Prophylaxis.

AMONG the details concerning the life, habits and predilections of the mosquito which recent inquiry has been the means of ascertaining is the exceedingly interesting observation of Messrs. Nuttall and Shipley on the preference exhibited by the *anopheles maculipennis* for certain colours, observations which cannot fail to influence the inhabitants of malarious districts in their choice of garments. They found, in the course of a long series of observations, that the insect exhibited a marked preference for cloths of navy blue, though dark red and reddish brown were not altogether distasteful. Scarlet and black were about equally attractive, though only to about half the extent of the others. Slate-grey, violet and leaf-green, on the other hand, were distinctly antipathetic to the mosquito, while the pale colours, especially light yellow approximating khaki, apparently excited positive aversion. These experiments, it is true, were made in Liverpool, and it would be rash to conclude therefrom that mosquitoes living in the open in other climes will exhibit precisely similar proclivities, but evidence is available from other sources to show that mosquitoes of all kinds are extremely sensitive to colour. For instance, it is a common observation that they affect black and blue garments in preference to white and yellow. Colonial authorities will doubtless be invited to reconsider their sumptuary edicts in view of the desirability of discarding uniforms made of cloths of colours which experience has shown to prove attractive to insects which play such an important part in the dissemination of malaria and yellow fever.

The So-called Lachnanthes Cure for Consumption.

THE "wonderful" treatment of consumption by the aid of lachnanthes, which Colonel le Poer Trench has so imprudently endorsed, has now been revealed to the profession in the columns of the *British Medical Journal*. Such at least is the purport of the paper by Mr. Anslow Alabone, although a doubt is thrown on the accuracy of the revelation by the disclaimer from Mr. Alabone *pere*, which appears in the current number of that journal, in which he asserts that he has no knowledge of his son's treatment, "and he little more of mine." After carefully reading the article contributed by Mr. Anslow Alabone, and admiring the extraordinarily complicated inhaler by the aid of which the combinations of drugs are administered to the patients in spray form, we can only wonder what it can be that brings about the wonders claimed for this treatment. On this point Mr. Anslow Alabone gives proof of a wise reticence. He himself, he says, is not yet in a position to certify the striking cures claimed for it by his senior, but he has adopted it "seeing the number of cases, he (the father) quotes as cured." By all means let the treat-

ment be thoroughly tried, the sooner the better, in order that it may cease to encumber the therapeutical field. If it has not been put to the test on a larger scale in the past it has been simply because its inventor has jealously kept it to himself. To suppose that the tuberculous process can be effectually stamped out or its course materially modified by the aid of these or any other inhalations, would be contrary to the incontrovertible data of pathological anatomy. The fuss that has been made about the thing is only another indication of the extraordinary gullibility of the unscientific public.

Club Certificates for Hospital Patients.

THE lack of a uniform practice in respect of giving club certificates to hospital patients has, on various occasions, given rise to complaints, and the authorities of St. Bartholomew's Hospital have now formulated certain rules which, it may be hoped, will remove any ground for criticism. It has been decided to deliver a certificate to each in-patient requiring the same on admission, and another on his discharge, the officials of the friendly societies having agreed to dispense with the usual weekly certificates in respect of inmates. A certificate will also be given to the victims of accidents who are not detained in the hospital. Out-patients will be referred to their club doctor, and in the event of the house surgeon being called upon to give such certificate, he will be entitled to make a charge of 1s. for it, such fee becoming the perquisite of the medical officer. Certificates required for the purpose of substantiating claims for compensation under the Employers' Liability Act are very rightly regarded as belonging to a different category. These rules are the outcome of prolonged deliberation, and were formulated after consultation with representatives of the principal sick benefit societies of the district, and it will probably be conceded that they meet every reasonable requirement.

Nurses and Matrimony.

ONE objection to trained female labour, however utilised, is that the service is liable to be disorganised by epidemics of matrimony among the employees. Nurses are by no means exempt from this weakness, and of late a disposition has shown itself in certain hospitals to discourage the admission of young women who are "engaged" on the ground that the fact of their future being thus mortgaged indisposes them to that self-abnegation and single-minded devotion to duty which are held to constitute the stock-in-trade of those who propose to take up nursing as a profession. It is to be feared that this proneness to matrimony which is innate in the female bosom cannot be checked by any precautions that jealous matrons or impatient physicians may devise. Were it possible, indeed, it would be contrary to public policy to enforce them, marriage being the natural, if not the invariable, destination of woman. Some may prefer the independence of the single state, but the majority assuredly only await the opportunity to disqualify themselves for the nursing profession.

The Journal of Obstetrics and Gynaecology of the British Empire.

THE first number of the new imperial *Journal of Obstetrics and Gynaecology* has appeared, and it certainly does credit to its editors and publishers. In the introductory remarks we are informed that the aim of the new journal will be to provide "a special journal independent of any society, devoted to the study of obstetrics and the pathology, diagnosis, and treatment of the diseases of women." That there is room for a journal which shall be in reality as well as in name a journal of obstetrics and gynaecology of the British Empire hardly admits of question. True, there are several flourishing societies in the Empire devoted to midwifery and the special ailments of women whose Transactions contain matter of high interest and value, but Transactions and society archives do not fulfil this ideal, indeed inclusion therein is in many instances almost equivalent to live burial. Original communications by Drs. Cullingworth, Horrocks, Berry Hart, Sinclair, Murdoch, Cameron and Arnold Lea, illustrated by some very artistic photogravures, diagrams and blocks, go to make up a number probably unique in point of scientific excellence. The number also contains a review of current literature and society transactions together with reviews. The editors will find it difficult to keep the publication up to this level, but if they even approximate it, the journal may claim to adequately represent British science in these special departments.

An Object Lesson in the Registration of Deaths.

AN instance of the scandalous ease with which certificates of death signed by unqualified persons are accepted by registrars came to light in the course of an inquest held last week by Mr. Troutbeck, Coroner for Westminster. It appears that the woman whose death was the subject of the inquiry had for several years been medically attended by one, Stanley, who described himself as having been the assistant of a deceased practitioner. On death taking place he delivered a certificate on a sheet of note paper to the effect that she had died of cirrhosis of the liver, and the registrar, with whom Stanley appears to have been personally acquainted, accepted it. At the inquest this officer declared that he considered the certificate to be "perfectly in order," and that it complied with the regulations of the Registrar-General. The only satisfactory feature in the case is the condemnation of such practices by the coroner and the rider appended by the jury to their verdict, calling the attention of the Registrar-General to the lax way in which the certificates of unqualified men are accepted.

WE regret to have to announce the sudden death from tetanus of Alderman Thomas Hyde Hills, L.R.C.P., M.R.C.S., of Cambridge. Mr. Hills was formerly Mayor of Cambridge, and was one of the foremost practitioners of that town.

The King's Sanatorium.

WE are enabled to impart the pleasing intelligence that an anonymous donor, who, we since learn, is no other than Sir Ernest Cassel, has placed at the disposal of his Majesty the sum of £200,000 for charitable purposes, and this sum the King has decided to devote to the construction of a sanatorium for the treatment of consumption. As soon as a fitting site has been obtained, a point to which his Majesty, assisted by a special advisory committee, is giving his special attention, the building of the sanatorium will be proceeded with. There is every reason to anticipate that the interest manifested by his Majesty in this question will act as a stimulus, and will be the means of providing in every part of the kingdom institutions for the reception of the afflicted, thus realising one of the desiderata formulated by the recent Congress on Tuberculosis. Sir Ernest Cassel is a successful financier of Jewish extraction, and his princely donation adds another to the list of magnificent charitable gifts which we owe to citizens of this race.

The Macclesfield Infirmary.

THE deadlock at the Macclesfield Infirmary has not come to an end with the resignation of Miss Clark. The medical staff, in order to avoid a repetition of a regrettable dispute, are disposed to insist on a revision of the constitution in such wise that in future it shall not be within the province of the governors to select candidates other than those previously approved by the honorary medical staff. A resolution to this effect is to be moved at the next meeting of the governors.

Accident to Professor Virchow.

WE regret to learn that the venerable Professor Virchow who, in October last, celebrated his eightieth birthday, has been the victim of a somewhat serious accident, due, it appears, to a stumble on leaving a tram car in motion, fracturing the neck of the femur and inflicting sundry extensive contusions elsewhere. The eminent professor, although he is stated to be in no actual danger, has sustained a shock which at his advanced age will necessitate prolonged rest and care. The last news from Berlin reports his condition to be fairly good.

The London Epidemic of Small-pox.

THE outbreak of small-pox in the metropolis is increasing steadily, and the returns show a progressively larger number of cases day by day under treatment in the Asylums Board Hospitals, the number actually in hospital being 837. A serious but hardly unexpected feature of this situation is the invasion of neighbouring counties. Among other districts thus involved are West Ham, Brentford, Sittingbourne, Great Stanmore, Gillingham, Enfield, and Ealing. The local authorities of the last-mentioned place appear to have been aroused to the fact of the miserably inadequate infectious hospital accommodation that is at present available for the

large population within their district. Small-pox has appeared in Glasgow, but it is not stated whether the outbreak is a recrudescence of the late epidemic, or whether it has been imported afresh from the metropolis or elsewhere.

The New Stamps and Infection.

THE new postage stamps of King Edward VII. are hardly calculated to arouse enthusiasm on the score of their artistic beauty and attractiveness. A medical contemporary has gone to the trouble of having analysed the pigments of their printed surface, and has come to the conclusion that they are practically harmless. It has always been more or less of a mystery how any practical men could suspect danger from minute quantities of arsenic or other poisonous matter used for the purpose of printing the stamp surface. The average individual contents himself with licking one side of the stamp only, and that is separated from the pigment by a layer, first of gum, and then of paper. That there is a danger of infection from postage stamps was long ago pointed out in THE MEDICAL PRESS AND CIRCULAR, which may take to itself any credit that arises from the introduction of the term "stamp-licker's tongue." The licking of gummed labels has been proved to have infected the tongues of workpeople, and a similar result may reasonably be regarded as a not impossible danger in the case of postage stamps. There are two ways in which infection might be thus conveyed, namely, by a virus contained in the substance of the gum, or by a contamination of its surface. In either case the poison is likely to be of a bacterial rather than of a chemical nature. It is a common thing to see a person outside a post office drop a postage stamp on the pavement and then pick it up and lick the label before affixing it to a letter. A better although a still imperfect plan would be to lick the envelope in preference to the stamp, but the sensible and safe way is clearly to use a sponge or felt moistener.

A Hospital Without an Operating Theatre.

AT the present day it is difficult to imagine a hospital without an operating theatre. Yet such we learn is the case at the County Galway Hospital. At the last meeting of the managers of this hospital Professor Pye, of the Queen's College, brought the matter under notice, and impressed, or tried to impress, on the managers the necessity that existed for such a theatre. To ordinary individuals the necessity for an aseptic modern operating theatre requires no laboured argument to carry conviction—not so in Galway. After a long and desultory discussion nothing was done. The managers could not see that such a theatre was for the benefit of the patients, neither could they understand that a good, well-attended medical school would benefit Galway.

THE offices of the London and Counties Medical Protection Society (Limited) have been removed to 31, Craven Street, Strand, W.C.

It is stated that the Friendly Societies are taking steps with the object of protecting themselves and the medical officers employed by them against the effect of the recent decision of the General Medical Council in the case of Dr. Rendall, of Yarmouth. With this object in view it is proposed to introduce a bill into Parliament during the next session making it libellous on the part of the Council to describe as "infamous" conduct which only amounts to a breach of professional etiquette.

PERSONAL.

MAJOR F. S. LE QUEENE, V.C., L.R.C.P., is now en route for South Africa, in medical charge of the Doncaster Militia. The Major, it will be remembered, was awarded the V.C. for gallant conduct in rescuing the life of a brother officer in India under a hot fire.

DR. J. MITCHELL WILSON, medical officer of health for Doncaster and district, having been appointed medical officer to the East Riding County Council, was presented on New Year's Day with a clock, a silver hot water jug and entree dishes by his medical and lay friends as a mark of their esteem.

SURGEON-GENERAL SKEY MUIR, C.B., who vacated his office as Deputy-Director-General of the Army Medical Service at the close of the old year, carries with him into retirement the good wishes of the many officers with whom he was brought in contact. His courtesy and amiability, often under trying circumstances, were much appreciated.

WE understand that the Government of the Orange River Colony have appointed Dr. Hine, late medical officer of health for Bradford and Sheffield, as medical inspector of the whole of the refuge camps within the colony, thus ensuring for the numerous occupants, of whose distress so much has been heard of late, the fruits of a ripe and extensive hygienic experience.

A MEMORIAL tablet was unveiled on Wednesday last in Moretonhampstead Parish Church to the memory of Frederick George Engelbach, for ten years medical practitioner in the town and first commanding officer of G Company 5th V.B.D.R., who was killed whilst succouring the wounded at the battle of Nooitgedacht, South Africa, Dec. 13th, 1900. The tablet was erected by the inhabitants as a token of regard.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDITORSHIP OF THE "SCOTTISH MEDICAL AND SURGICAL JOURNAL."

DR. RUSSELL intimates, in the January number of the *Scottish Medical and Surgical Journal*, that his resignation of the editorship is in the hands of the directors. The *Journal* was founded five years ago, at the time when the *Edinburgh Medical Journal* changed hands, by a number of medical men in the different educational centres in Scotland, who became guarantors for a period of three years. On the expiry of this period the guarantors sold the journal to a limited liability company, receiving in exchange ordinary shares to the extent of the amount of the guarantee called up. Dr. Russell has edited the *Journal* since its commencement, and was joined two years ago by Dr. Norman

days. Coke can be lighted easily enough by merely laying the foundation of the fuel in a burning stratum of ordinary coal; and when once the coke on the top of that is ignited the flame will soon spread throughout the grate until it becomes one glowing mass. A coke fire never, alas! admits the "pleasure of poking," but the fire is the better for clearing the lowest bar of the grate by a thin iron rod from time to time in order to get rid of the fine dry dust which accumulates upon it.

I am, Sir, yours faithfully,

CHARLES A. COOKSON.

96, Cheyne Walk, S.W.

Obituary.

DR. WILLIAM NEALE.

It is with sincere regret that we announce the death of Dr. William Neale, of Mountmellick, of which he was the medical officer for the workhouse and dispensary district. The deceased gentleman was a member of one of the oldest families of the Society of Friends in the county, and was universally respected for his uniform courtesy and unvarying gentle kindness to the sick. As a physician he was observant, painstaking, and skilful, rich in clinical experience and fertile in expedients. He wrote but little, but when he did his papers were remarkable as good clinical pictures, lucid and instructive, as his contribution "Epidemic Sore Throat and Diphtheria," which appeared in our columns, shows. Dr. Neale graduated in Dublin in 1871, and took the L.R.C.P. Edinburgh in 1874. Before settling down to a country practice he acted as medical officer on the White Star Transatlantic steamers, then got appointed medical officer to Clonane, and finally was appointed both to the workhouse and the dispensary district of Mountmellick. He was a general favourite, and when some years ago it was announced that he had been made a J.P. for the Queen's County, the appointment gave universal satisfaction.

CHARLES ROBERTS, F.R.C.S.

MR. CHARLES ROBERTS, F.R.C.S., formerly of Curzon Street, Mayfair, and Devonshire Place, Eastbourne, a writer on meteorology, phrenology, and anthropometry, died on Tuesday of last week at his residence, Silverdale, Boyne Park, Tunbridge Wells. He had been assistant surgeon to the Royal Victoria Hospital for Children, house surgeon to the Yorkshire County Hospital, and surgeon to the Yorkshire County Prison. Among his better-known works were "A Manual of Anthropometry," "The Detection of Colour-blindness and Imperfect Eyesight," "The Naturalist's Diary: a Day-book of Meteorology, Phrenology, and Rural Biology," "Medical Inspection of and Physical Education in Secondary Schools," and "Eastbourne as a Health Resort." He had also contributed some valuable papers to the St. George's Hospital Reports and the professional journals.

Lunacy Department.

ASYLUM REPORTS (continued).

ROXBURGH, BERWICK, AND SELKIRK DISTRICT.

The total expenditure up to date of Report was £96,726 7s. 4½d.; the expenditure during the year upon the asylum buildings, new laundry, furniture, &c., having amounted to £3,696 17s. 2½d. There had lately been erected at the asylum an iron escape stair, and the Board had resolved to erect during the current year three additional cottages for the accommodation of married members of the staff, also a boiler-house with new boilers, &c., smith's shop, and coal store. As the male department of the asylum is overcrowded the Board contemplates the erection of a hospital for male patients requiring such treatment. The rates of board are rather high. They have always been high in this asylum, but we are sure that Dr. Johnstone sees that his patients are well looked after and that the

money is well expended. Of course, of late years we know that the rate of board has had to be high in all asylums, because of the high price of coal and food stuffs. Then salaries and wages are on the increase here, as in all other departments of labour, and a serious question has arisen, namely, the salaries of medical officers. Dr. Carlyle Johnstone, in his report, touches incidentally on the subject of pensions. We wish he had said more, but asylum officers, like the coney, are a feeble flock, their influence is small, their political power nil, and they are helpless in the matter, unless some strong man at headquarters takes up this subject. The extensions and alterations have given great satisfaction.

MULLINGAR DISTRICT.

It is a matter for regret that the influx in the past year was almost entirely composed of females, which tended to seriously cramp the already overcrowded space in the female divisions. The female section now finds breathing space for sixty-four patients more than it ought to contain. This is much to be regretted, and the Board should lose no time in providing adequate accommodation. One feature—the introduction of apprentices in the works department, is worthy of special notice. The apprentices are legally bound to the various tradesmen. The recovery rate has been somewhat lower, and the death-rate higher. The Committee interdicted the sending of patients to outside entertainments without their sanction. This is a matter which we think should be left within the discretion of the medical superintendent. The enjoyment derived on such occasions is often far in excess of what one would anticipate. The Committee, on the score of economy, have ordered the supply of daily and illustrated papers to be discontinued. Nowadays newspapers are regarded as almost a necessity of life. What must this necessity be among a class deprived of liberty? We hope the committee will see the injustice of their action, for asylums, as a rule, are apt to be overlooked in this respect. Phthisis as a cause of death appears in 41 per cent. of the cases—a very high average.

CHESHIRE COUNTY.

There is nothing of more than local interest in this report, but there is evidence of good work being done. A large greenhouse has been erected and this will meet a much-felt want. Plants have a great effect in making the wards of an asylum look bright and cheerful. The Commissioners, on their visit, gave a false fire alarm and in two minutes the men had hose ready to play on a supposed fire on the stage. The recovery rate (44.20 per cent.) is the highest that has been reached during the last ten years, and the death-rate (7.54 per cent.) is the lowest recorded for at least thirty-six years—a very satisfactory state of affairs. As regards the causes of death, general paralysis and phthisis appear respectively in about 20 and 18 per cent. of the cases. In 14 per cent. of the admissions the cause of insanity is recorded as due to intemperance.

DOWN DISTRICT.

This is a very full and complete report, containing one or two interesting illustrations of the interior of the asylum. The total admissions for the year, 149, is twenty-one in excess of the previous year. The recovery rate—37.6 per cent. on the admissions—is satisfactory. The deaths number no less than sixty-one—an unusually high death-rate. Phthisis, heart disease, and dysentery are responsible for half of them. Like many others, this asylum had to contend with an epidemic of influenza of an acute character. Unfortunately, dysentery was also in painful evidence, and, although strong measures were adopted to limit its spread, twenty-two persons were affected, of whom four died. From the earliest years in the history of this asylum it would appear this disease had been intermittent in its visitations, and it is much to be regretted that the cause is still undetermined, in spite of the unstinted labours of Dr. Nolan to get at the bottom of it. The want of an isolation hospital was much felt. The amusements of the patients receive special attention, and this is just as it should be, but

the system of employing temporary attendants to replace those on leave is most undesirable.

GLOUCESTER COUNTY.

The committee call attention to the increase—no less than forty-five in the number of patients chargeable to the county. This increase is attributable to an extraordinary low death and a diminished recovery rate, a large portion of incurable cases having been admitted during the year. Of the admissions, 22 per cent. were over 60 years of age. Here, as elsewhere, it is being forced on the notice of the authorities that asylums are not now regarded *bona fide* as asylums. It has been necessary to raise the charge for maintenance to 9s. per week. The Commissioners in their report, which is very satisfactory, disapprove of the Clerk of Works being in possession of a key admitting him to the female side. Dr. Craddock's report is a lengthy one, but it does not contain much beyond local interest.

DORSET COUNTY.

This report is full of detail, and in some respects interesting. The Committee have had under their serious consideration the question of the growing want of accommodation on the female side. This matter was earnestly brought under their notice fully two years ago by the Commissioners. The rate of board has been increased from 8s. 9d. to 9s. 4d. per week. An out-patient department has been established, and this will no doubt prove a boon to many deserving poor. The cause of insanity in 50 per cent. of the admissions was due to heredity, and in 1·8 per cent. to alcohol. The high percentage of heredity and the very low percentage of alcoholic cases makes those figures specially interesting. They do not bear out the truth of the statement that, where hereditary predisposition is common, a high percentage of alcoholic cases is sure to be found. Heredity, as a cause of insanity in Dorsetshire, has been the subject of much comment. The dietary is varied, but two courses each day at dinner are more desirable, and would better meet individual tastes.

Literature.

ROBERTS ON GYNÆCOLOGICAL PATHOLOGY. (a)

THIS is a book of some 300 pages, with 151 illustrations, the object of which is to give a simple account of the morbid processes to which the female organs are subject. It gives a fairly good account of most of these processes, and includes some clinical details of the subject with which it deals.

Some of the author's statements are not in accord with the views of good authority, the histological descriptions are not always sufficiently full and clear to be of any practical utility, and there are some subjects which do not receive the attention they appear to us to deserve. We are not able to agree with the author in his classification of proliferous cysts of the ovary.

What he describes under that heading as simple multilocular cyst, "in which there has been distension of many of the follicles," appears to us not to belong to the proliferous cysts at all, but to be merely multiple follicular cysts in which there is no epithelial proliferation. Though "papillary" cyst is a common term, we think that "papilliferous" cyst expresses the character of these growths more clearly.

No mention is made of the more solid complex dermoids, or teratoid tumours, which, though uncommon, are of great pathological and clinical interest, as we believe most of those placed on record have behaved as malignant tumours. Dr. Roberts considers the so-called chronic endometritis is not an inflammatory process at all. With this view we quite agree, though no doubt the incorrect term will have the long life that such terms often have.

We do not think, however, that the condition can be any more correctly termed adenoma, as is suggested by him. Adenoma appears to us to denote a distinct

tumour, such as does not occur in these cases, and, moreover, the so-called endometritis is sometimes entirely an interstitial growth, and not at all glandular. Fig. 17, which is described as being "really an adenoma," does not convey any such idea to our mind. We think the term hyperplasia, glandular or interstitial, according to the character of the newly-formed tissue, is much to be preferred.

We find only a casual mention of adeno-myomata. Such tumours are not very uncommon, and are subjects of considerable pathological interest. In view of the researches of Recklinghausen and others, we think they deserve much fuller consideration than they receive from Dr. Roberts. We do not agree with the author that a zone of transitional epithelium occurs at the junction of the squamous epithelium of the portio vaginalis and the columnar epithelium of the cervix.

In our experience such a zone does not exist, and even if transitional epithelium has been found in this situation, surely the statement that "the transitional epithelium is a narrow and debatable belt of cubical cells with a few glands," is a mistake.

The author appears to doubt the existence of sarcomatous degeneration of uterine myomata, and considers so-called cases have been sarcomatous from their beginning. There are many able pathologists whose opinion is opposed to his on this point.

We ourselves have several times seen cases in which a uterine tumour was microscopically sarcoma in one part and myoma in another, and we think the most rational explanation of such an occurrence is that a myoma has undergone sarcomatous change.

Considering the great importance attached, and rightly attached, in recent years to the microscopical diagnosis of tissue removed by the curette, we should have expected in a book of this class a fuller account of the histology of malignant diseases of the uterus.

The author calls attention to the difficulty that sometimes arises in the differential diagnosis of neoplasms, and to the considerable knowledge of uterine histology which is often necessary in arriving at an opinion.

We do not think the difficulty of diagnosis is greater in the case of uterine neoplasms than is the case with similar tumours in other parts of the body, and we cannot agree with Dr. Roberts in his statement that "the terms" (epithelioma, carcinoma, sarcoma) "used simply indicate certain pathological tendencies." On the contrary, we consider these terms imply a certain histological structure, and a certain origin.

The author considers the syncytial theory of the origin of the so-called deciduoma malignum unnecessary, and adopts the view which is generally taken in England, that these tumours are sarcomata. He states that "the great majority of cases of so-called deciduoma malignum ought to be classed as rapidly-growing sarcomata." We should like to have had a statement of his opinion as to the nature of the minority of these cases. We have no doubt that cases of sarcoma have been erroneously described as deciduoma, and some of the cases related by Dr. Roberts may have been wrongly referred to this class. Indeed, in one of them the histological structure is not described, but we are told that a microscopical diagnosis of epithelioma was arrived at early in the case. No doubt cells resembling the syncytium do occur in sarcomata, but we cannot recall any tumour where such differences between the constituent cells existed as exists between the two varieties of cells found in deciduoma, both in regard to their protoplasm and their nuclei.

The resemblance these two varieties of cell have to those covering the chorionic villi would suggest that they originated from these; and the fact that in cases described by Neumann, and by Gebhard, a chorionic villus was found, and the connection of the tumour cells with its epithelium traced is a strong evidence that these cells have a similar origin in other cases. The structure of these tumours is not well described, and no mention is made of the occurrence of deciduoma in the Fallopian tube, a condition of which at least one case has been recorded.

(a) "Outlines of Gynecological Pathology and Morbid Anatomy." By C. Hubert Roberts, M.D. London: J. and A. Churchill.

The book closes with a useful chapter on micro-organisms in connection with gynecological pathology. The illustrations are mainly original, and most of them are exceedingly good, but the composite diagrams of micro-organisms, especially that of the gonococcus, are not of any practical value.

There are numerous footnote references to the works of the authors whose opinions are cited.

ALLCHIN'S MANUAL OF MEDICINE.—VOL. III. DISEASES OF THE NERVOUS SYSTEM.(a)

IN approaching the criticism of this volume of Allchin's Manual of Medicine, which deals with diseases of the nervous system, it is well to bear in mind that the subject in question has attained a high degree of specialisation. As yet it is impossible to reduce this branch of study, with its host of details, to the level of absolutely clear deduction and generalisation. The task before the editor of an up-to-date treatise upon the subject, therefore, is no light one. On the whole, we should say the volume before us is one of the best of the kind we have yet seen. In spite of that opinion, however, we feel it a duty to remark that there are many important points omitted, so much so that a candidate for the higher medical qualifications might well be "ploughed" if he possessed no knowledge derived from sources other than the present volume. Sherrington's article on spinal segments appears needlessly complex; it is certainly difficult to follow, and would be practically useless to students for examination purposes. Tumours of the brain and focal diagnosis, however, by Aldren Turner, is well done, and much of the information arranged in tabular form. In *tabes dorsalis* no information is given as to the origin or meaning of the word "*tabes*," and no reference is made to the fact that the disease was formerly and is still not uncommonly known as "progressive locomotor ataxy." The term, it is true, is objectionable on every ground, but still the student should know it has been so used. Visceral crisis (p. 197), trophic changes (p. 198), and the condition known as hypoloma are well described, but there is no anatomical explanation given of the Argyll Robertson pupil. Pseudo-hypertrophic paralysis (p. 213) would be better for an illustration, showing the characteristic attitude, a remark that also applies to paralysis agitans. Under the latter disease we find no mention of the "Parkinson mask"; at any rate it is not mentioned in the index. In tetany (p. 316) too little importance is attached to the connection with dilatation of the stomach, and other gastric disorders. Possibly the article was written before the appearance of a certain recent work on the subject. There is some difficulty in readily ascertaining the authorship of any particular article. In the list of contents the authors' names are not given and the articles are not each of them signed, but a signature is appended to a group of articles. Take syringomyelia for example (p. 191): one has to turn over some twenty pages to find out that it is written by Dr. Ormerod. In our opinion the plan followed in Clifford Allbutt's "System" is better, namely, that of appending the name of the writer to each subject. Some of the best articles in the book are by Dr. Purves Stewart. It is almost a pity he was not entrusted with the article on chorea, in which he has done some good original work. The work done by Bertram Abrams is clear and carefully written. In the account given of *tic-douloureux* (p. 278) there is nothing said, so far as we have been able to discover, about "convulsive tic," a subject to which several pages are devoted in Allbutt's "System of Medicine." The student would be puzzled by such words as "*coprolalia*" and "*latah*," which would indeed be Malay to him. Neurologists, it is recognised, employ a language of their own, and the value of a work for those who are not specialists on the subject would be enhanced by an explanation of new and strange terms. On the whole, as we have already said, the book is a

good one, and in our opinion is an advance on previous volumes of the same series.

KITCHEN PHYSIC. (a)

THIS is no formal treatise on dietetics—it is addressed at least as much to the public as to the profession "at hand for the doctors and helpful for homely cures." It is full of curious and useful information, well diluted with literary meanderings and antique souvenirs. But as a factor in the maintenance of health and in the case of disease it is by no means a new science; indeed, its origin dates back beyond the dawn of history. The author has diligently studied the literature of the past, and his text is replete with old wives' sayings and popular adages in respect of the curative properties of particular articles of diet. After a few chapters of a more or less dilettante style the author settles down to his task and epitomises all that is worth knowing in the matter of special diets for particular diseases and conditions. He reinforces his maxims by the aid of sundry doggerel rhymes culled from poetically disposed physicians and dieteticians of the past, and throughout he writes in a genial, untechnical way which cannot fail to find favour with the public. Although the author is careful to place himself on the level of a certain section of his readers, we can cordially recommend his work to the notice of practitioners who, it is to be feared, are not, as a class, by any means over-skilful in the management of this very important department of therapeutics. Physicians, moreover, are in a position to winnow the grain from the chaff, the latter, in more senses than one, being present in rather stiff doses. The author writes in such a happy strain that we have not the heart to criticise in the matter of detail. He seems to say: "Here is all I have been able to find out about it, and now make your choice." It is a work which ought by right to find a place on the shelves of every housewife's domestic library, and, as already observed, it is not unworthy of a place alongside of the more severely technical treatises on dietetics. A medical man who could turn its precepts to account in practice would certainly command the respect, nay, the admiration, of his patients in an age when dietetics, like prescribing, threatens to become a lost art. The volume comprises close upon six hundred pages, and there is not one we could willingly spare.

SANITARY INSPECTORS' HANDBOOK. (b)

ALTHOUGH the little work before us has no very great claims to originality, and is, in some respects perhaps, rather unduly drawn out, it nevertheless contains much practical information of use to the average inspector of nuisances. We cordially endorse the writer's plea for fixity of tenure of these appointments, and can only hope that the Local Government Board will encourage as far as possible in the future those public bodies willing to appoint their inspectors permanently, irrespective of whether they devote the whole of their time to their duties or not. The "Alphabetical Synopses" of the Public Health Acts is well drawn up, and should prove a very handy means of reference. In the chapter on House Drainage we notice the following. Speaking of Doulton's Composite Joint, the writer remarks that this joint "allows where necessary deviation from the straight line in laying." It is to be regretted that he should lend the weight of his authority to such a procedure, as we have frequently found builders only too ready to save themselves trouble by laying drains with these improperly constructed bends, a plan certainly not to be countenanced in any way. We also find ourselves unable to concur in the author's condemnation of the Local Government Board's model bye law regarding sink and other waste pipes, as surely it is much better practice that grease should collect in the open channel, where it is seen and can be easily removed, than that it

(a) "A Manual of Medicine." Edited by W. Allchin, M.D. Lond., F.R.C.P., Senior Physician Westminster Hospital, &c., &c. Vol. III. (London: Macmillan and Co. Price 7s. 6d.)

(a) "Kitchen Physic." By W. T. Fernie, M.D. (Bristol John Wright and Co., 1901. Price 6s.)

(b) "The Sanitary Inspectors' Handbook." By Albert Taylor Third Edition. Pp. 408. Cr. 8vo. Price 6s.

should accumulate under the grating of a grease trap, where, being out of sight, it is also out of mind; while, further, where the latter plan is adopted, some may be swept out into the drains, and there deposited, causing them to become foul and impeding the full flow of water, &c., through them. A considerable portion of the chapter on "Drain Testing"—one of the most important subjects for a sanitary inspector to be skilled in—is devoted to the purely negative smoke and pungent chemical tests; while the pneumatic test, which is probably the most trustworthy, is passed over with a mere cursory mention. Infectious diseases and disinfection are well and concisely dealt with, though for the benefit of those inspectors who have not the assistance of an expert engineer a more detailed account accompanied by plans of some form of disinfecter would be useful. We also observe that the writer has omitted any reference to refuse destructors, some knowledge of which is certainly desirable to many sanitary inspectors. Useful hints on ventilation and allied subjects are given, while the chapters on meat inspection and slaughter-houses could hardly be improved on in a work of this sort. The remainder of the book contains much that is valuable, more especially that portion dealing with the Sale of Food and Drugs Acts. There is perhaps rather too much tendency shown all through to elaborate legal decisions, nor can we regard a dissertation on the "properties" of bye-laws as of much import to a sanitary inspector, whose duty it is merely to administer such under the direction of his authority. The little work is well illustrated with numerous and useful cuts, though we should hardly have thought it necessary to devote a whole page illustration to the obsolete pan closet and D trap, while with one or two exceptions the language employed is clear and concise, and, generally speaking, the book should prove of considerable value to that class of public servant for whose benefit it has been written.

Medical News.

Court-martial on a Fleet Surgeon.

A COURT-MARTIAL was held on board the *Fort* at Chatham on Friday last, for the trial of Fleet-Surgeon Robert William Anderson, who was charged with having neglected his duty in respect of a stoker who had died of pneumonia, and with having failed to conform to the regulations requiring him to visit the sick twice a day and oftener if necessary. It seems that the accused officer was absent on short leave, and had gone to Newcastle, so that he did not see the patient until the day after his admission. The early symptoms did not present any evidence of the gravity of the case, but the Court held that the accused, who declined to give evidence on oath, was guilty of the charges brought against him, and sentenced him to be severely reprimanded and dismissed his ship.

A Medical Victim to the Chloroform Habit.

An inquest was held in South London last week on the body of Henry Carrington, L.E.C.P.I., of Battersea Rise, S.W., who had succumbed to chloroform poisoning. It appeared that the deceased was in the habit of inhaling chloroform on retiring to rest, and it was surmised that he had taken an excessive dose by accident. A verdict of "Death by misadventure" was returned.

The Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity, and Life Assurance Society was held on the 27th ult., at 429, Strand, London, W.C. There were present Dr. de Havilland Hall, in the chair; Dr. J. B. Ball, Dr. Frederick S. Palmer, Dr. Walter Smith, Dr. St. Clair B. Shadwell, Mr. F. S. Edwards, Dr. F. J. Allan, and Dr. W. Knowles Sibley. The accounts show that the society is still growing in numbers, notwithstanding the keen competition to which it has of late years been subjected by institutions doing the same class of business but paying liberal commission for the introduction of new members. The committee have never felt justified in doing this, but by the economical manner in which they have worked the

society have been enabled to provide the members with such useful benefits that the latter have willingly acted as unpaid canvassers and brought the society under the notice of their professional friends. In this way it has grown in numbers and financial strength, while the contributions of the members have been devoted to affording them a liberal allowance when sick. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

Vital Statistics.

THE deaths registered in the week ending December 28th in 37 large towns of the United Kingdom corresponded to an annual rate of 18.5 per 1,000 of their aggregate population, which is estimated at 11,463,026 persons in the middle of this year:—

Belfast 22, Birkenhead 18, Birmingham 23, Blackburn 21, Bolton 19, Bradford 18, Brighton 18, Bristol 19, Burnley 26, Cardiff 20, Croydon 21, Derby 14, Dublin 26, Edinburgh 22, Glasgow 24, Gateshead 18, Halifax 17, Huddersfield 25, Hull 18, Leeds 21, Leicester 21, Liverpool 22, London 20, Manchester 29, Newcastle-on-Tyne 19, Norwich 17, Nottingham 22, Oldham 19, Plymouth 18, Portsmouth 18, Preston 22, Salford 24, Sheffield 20, Sunderland 18, Swansea 19, West Ham 19, Wolverhampton 18. The highest annual death-rates per 1,000 living, as measured by last week's mortality, were:—From measles, 1.8 in Sheffield and in Sunderland, 2.4 in Manchester, 3.3 in Norwich, and 6.5 in Preston; from whooping-cough, 1.1 Liverpool and in Burnley, and 2.2 in Leeds. In none of the large towns did the death-rate from scarlet fever, from "fever," or from diarrhoeal diseases reach 1.0 per 1,000. The 75 deaths from diphtheria included 28 in London, 7 in Burnley, 5 in Birmingham, 4 in Birkenhead, 4 in Liverpool, 4 in Sheffield, 3 in West Ham, and 3 in Leeds. Twenty-five deaths from small-pox were registered in London, and 2 in West Ham, but not one in any other of the large towns.

Fire on a Small-pox Ship.

AN outbreak of fire which might easily have had very serious consequences occurred on the *Endymion*, one of the three isolation hospital ships moored in the Thames, at Long Reach, off Dartford, on the night of the 2nd inst. It was not until many hours had passed that the fire, which had broken out in the stokehole, was got under. The *Endymion* furnishes sleeping accommodation for the nurses, and lies between the two other vessels.

University of London.

AT the B.S. Examination for Honours, the following candidates were successful in:—

Surgery.—First Class.—Felix Bolton Carter, M.D.; Arthur Edmunds, B.Sc. (scholarship and gold medal); Thomas Copeland Savage (gold medal). Second Class.—Charles Archibald Scott Ridout, Ralph Paul Williams W. Halliburton McMullen. Third Class.—Ernest Lewis Lilley.

University of Dublin.

AT the winter commencements, Michaelmas Term, held on Thursday, Dec. 19th, 1901, in Trinity College, the following degrees in medicine, surgery, and midwifery were conferred by the University Caput in the presence of the Senate:—

Baccalaurei in Medicinâ, in Chirurgiâ, et in Arte Obstetriciâ.—R. H. Atkins, H. Crossle, J. E. Collins (B.Ch. stip. cond.), S. J. Callum, J. H. Douglas, E. D. Edwards, W. F. Erskine, M. J. Gibson, R. E. Halahan, A. L. Hoops, A. E. B. Jones, K. W. Jones, C. S. Miller, G. F. White.

Doctores in Medicinâ.—C. K. Bushe, J. J. Crawford, G. Fitzgibbon, W. S. Haughton, J. W. Hillier, T. D. Homan, H. E. Littledale (stip. cond.), T. P. McKell, H. H. Orr, M. J. Smith, J. Tichborne, G. F. White.

Society of Apothecaries of London.

THE following candidates passed the primary examination, Part II., on Dec. 30th, 1901, Jan. 1st and 2nd, 1902:—

Anatomy.—H. Bennett, J. Cree, T. L. A. Jones, P. J. Martin, and E. Renouf.

Physiology.—J. Cree, E. P. J. Dawes, A. G. C. Findlay, E. Renouf, F. A. K. Stuart, and T. R. Waltenberg.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

THE WILLIAM SMYTH MEMORIAL FUND.

WE learn that the William Smyth Memorial Fund is to close on February 1st. The treasurers of all local funds through the country are requested to forward their lists of subscriptions for publication in the papers, and to lodge the various amounts to the credit of the Fund in the Bank of Ireland. Among the largest subscriptions to the Fund has been one of ten guineas from Sir Henry Irving. We need not dwell again on the services which Dr. Smyth rendered to his fellow-men, and on the duty of assisting to support in dignity and comfort the wife and family he has left behind. It is sufficient to direct the attention of those who wish to subscribe to the fund but have not already done so to the date at which it is proposed to finally close the list.

A SOUTH AFRICAN SUBSCRIBER will find his requirements fully met in Surgeon-Capt. Munson's "Text-book of Military Hygiene." It is a big volume, but we know of no smaller book that answers our correspondent's needs.

MR. GRESSWELL.—It will afford us pleasure to carry out the suggestion when opportunity offers.

APPROACHING THE END.—TRANSVAAL MEDICAL REGULATIONS.—A proclamation has been issued in Pretoria making provision for the admission of medical practitioners to the Transvaal. It contains a clause preventing the issue of licences to applicants holding foreign diplomas unless the laws of the country in which the diploma is conferred grant equivalent privileges to qualified British practitioners.

THE MENTONE MANIFESTO.

REFERRING to our comments on the refusal of a majority of the hotels at Mentone to receive visitors with consumptive tendencies, the proprietor of "The Hotel Britannia" writes us that both his wife and himself are British subjects, and that they would not think of shutting the door of their hotel against invalids, unless, of course, their disease was of a too pronounced type. They add that previous experience of guests with these tendencies have shown them that they quickly improved in health with the air of the Riviera, and the "Manifesto" notwithstanding, physicians need not hesitate to send patients who are not in an advanced stage.

RES ANSERINUS.—The protest is a ludicrous one, and is not worthy of notice.

F.R.C.S. Eng.—For some reason the College of Surgeons, Eng., have not forwarded a list of the successful candidates, for publication, at the examination for the Fellowship held in November, 1901.

PHOTOPATH.—You will find all the information you require, and much besides, in Wellcome's "Photographic Exposure Record and Diary" for 1892 (Burroughs Wellcome and Co., London), price 1s. You must be careful to obtain the Southern Hemisphere Edition, which is specially compiled for your latitudes.

DR. J. M. S.—The donor of the £200,000 to the King's Hospital Fund is Sir Ernest Cassel, the successful financier.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, JAN. 8th.

DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.). 5.15 p.m. Demonstration of Cases of Interest. SOCIETY OF ARTS.—5 p.m. Sir Henry T. Wood; Photography and its applications. (Juvenile Lecture.)

THURSDAY, JAN. 9th.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Annual Meeting. The President: Valedictory Address. Specimens will be shown by Dr. J. A. Mansell Moullin and Dr. F. Purcell.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8 p.m. Annual General Meeting. Election of Officers. President's Address. Annual Conversation.

FRIDAY, JAN. 10th.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers: Mr. A. W. Mayo Robson: The Radical Treatment of Chronic Tuberculosis of the Intestines. Mr. E. P. Paton: A Case of Hair-ball removed from the Stomach of a Child of nine years. Mr. H. W. Page: Two Cases of Arthritis of the Knee and Leg, with an Investigation into the Pathogenesis by Dr. A. Paine and Dr. F. J. Poynter.

INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH (9, Adelphi Terrace, W.C.).—7.30 p.m. Meeting. 8 p.m. Mr. D. S. Davies: Plague Exclusion and Control.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square, W.).—4.30 p.m. Annual General Meeting. 5 p.m. Ordinary Meeting. Cases and Specimens will be shown by Dr. Bronner, Dr. S. Spicer, Dr. Thorne, Dr. Horne, Dr. Sharman, Dr. Milligan, and Dr. St. Clair Thomson.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSO-

CIATION (11, Chandos Street, Cavendish Square, W.).—4 p.m. Cases will be shown and papers read by Mr. C. Woakes, Dr. W. Wingrave, Mr. A. Thorne, Mr. Lennox Browne, Mr. M. Collier, and others.

DUBLIN.

THURSDAY, JAN. 9th.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION (Front Hall, Trinity College).—8.15 p.m.

FRIDAY, JAN. 10th.

ROYAL ACADEMY OF MEDICINE IN IRELAND (Section of Pathology, College of Surgeons).—8.30 p.m. The President: (a) Remarks on the Present State of our Knowledge as to the Etiology of Vaccinia (with lantern slides); (b) Remarkable Cyst of Lesser Peritoneal Cavity; (c) On the Condition of the Heart in a Case where Death occurred during Anæsthesia. Mr. J. P. Doyle: Disease of two Upper Cervical Vertebrae and upper part of Left Humerus.

Appointments.

BODY, HENRY MARTIN, M.R.C.S., L.S.A., Medical Officer for the Sandford District of the Crediton (Devon) Union.

BOON, J. G., L.R.C.P.I., L.R.C.S.I., Certifying Surgeon under the Factory Acts for the Borough of Wenlock, in the county of Salop.

DARIN, T. B., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory Acts for the Uxley District of Lincolnshire.

FENWICK, CHARLES, L.R.C.P., L.R.C.S. Edin., Medical Officer for the Cheriton Bishop District, Crediton Union.

GOADBY, KENNETH W., L.D.S. Eng., D.P.H. Camb., Bacteriologist and Lecturer on Bacteriology to the National Dental Hospital.

GREEN, FREDERICK RICH, F.R.C.S. Eng., L.S.A., Honorary Consulting Surgeon to the Royal United Hospital, Bath.

HALL, J. N., M.R.C.S., L.R.C.P. Lond., Medical Officer of the May field District of the Uckfield Union.

LACK, H. LAWRENCE, M.D. Lond., F.R.C.S., Aural Surgeon to the London Hospital.

M'KENNICK, G. BROWNE, F.R.C.P., F.R.C.S. Edin., L.F.P.S. Gha., to take charge of the Department for Kidney and Urinary Diseases in the Glasgow Public Dispensary.

PANDOL, JOHN, M.B., M.R.C.S., Surgical Assistant to St. Peter's Hospital, Covent Garden.

RIDOUT, C. A. S., M.B., B.S. Lond., M.R.C.S., L.R.C.P., House Surgeon to the North Staffordshire General Infirmary and Eye Hospital, Stoke-on-Trent.

SCOTT, EDWARD JAMES HERBERT, F.R.C.S. Edin., Honorary Consulting Surgeon to the Royal United Hospital, Bath.

SMITH, G. U., M.B. Lond., Bacteriologist to the Cambridge Town Council.

Vacancies.

Belmullet Union.—Medical Officer. Salary £100 a year, and £10 a year as Medical Officer of Health, together with Registration and Vaccination fees. Applications to E. N. Flynn, Clerk of the Union. (See advt.)

Birmingham General Dispensary.—Resident Surgeon. Salary £150 per annum. Furnished apartments, fire, lights, and attendance. Applications to Ernest W. Forrest Secretary.

Bootle, Borough of, Hospital for Infectious Diseases. Resident Medical Officer. Salary £120 per annum, with board, washing, and apartments at Hospital. Applications to J. Henry Farmer, Town Clerk's Office, Bootle. (See advt.)

Bradford Royal Infirmary.—Dispensary Surgeon. Salary £100 per annum, with board and residence. Appointment for twelve months, renewable. Application to William Maw Secretary.

Carlou Union.—Temporary Medical Officer. Salary three guineas per week, to include car hire. Applications to the Presiding Chairman, care of Thomas F. Coyle Assistant Clerk of the Union. (See advt.)

Hampstead Hospital.—Resident Medical Officer. Salary £120 per annum, with rooms, coal, and gas. Applications immediately to E. A. Orwhaithe, Hon. Secretary.

Hemel Hempstead, West Herts Infirmary. House Surgeon and Assistant Secretary. Salary £100 per annum, with furnished rooms, board, fire, lights, washing, and attendance. Applications to the Hon. Secretary at the Infirmary.

Joint Counties Lunatic Asylum for the Counties of Brecon and Radnor.—Medical Superintendent for the new Asylum at Talgarth. Salary £450 per annum, with partially furnished house, coal, light, washing, and garden produce. Applications to Henry F. W. Harries, County Hall, Brecon.

Lancashire County Asylum, Winwick, Newton-le-Willows.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

London Hospital, Whitechapel, E.—Assistant Director of the Pathological Institute at this Hospital. Salary £200 per annum. Applications to G. Q. Roberts, House Governor.

Salop County Council.—Medical Officer of Health. Salary £750 per annum. Applications to E. C. Beale, Shirehall, Shrewsbury.

Whitechapel Union Infirmary.—First Assistant Medical Officer. Salary £150 per annum, all found. Forms of application to be obtained from William Vallance, Union Offices, Vallance Road, Whitechapel, N.E.

Births.

GIBSON.—On Jan. 3rd, at 3, Queen's Crescent, Glasgow, the wife of E. Arthur Gibson of a son.

SANSON.—On Jan. 1st at the Glen, West End Lane, West Hampstead, N.W., the wife of H. Arthur Sanson, M.D. Lond., of a son.

Deaths.

FROLIOTT.—On Jan. 3rd, at Little Missenden Vicarage, the Rev W. Frolliott, third son of Francis Frolliott, M.D., of Clonabity, co. Cork.

The Medical Press and Circular.

A CASE OF ACQUIRED DEAF MUTISM, PROBABLY DUE TO CERUMEN. RAPID RECOVERY OF HEARING AND SPEECH ON REMOVAL OF CERUMEN.

By MAYO COLLIER, M.S.LOND.,

Senior Surgeon to North-West London Hospital, &c.

MARY M., æt. 9, was sent to the hospital on December 5th, with a note from a lady who took an interest in the child, asking me to kindly examine the little girl and tell her if anything could be done as she was apparently deaf and dumb.

The mother, who accompanied the child, stated that quite early in life when a baby she was bright and intelligent, and not unlike her other children, whose hearing was good and whose speech was not defective. At the age of two years the child had typhoid fever severely, from which she apparently recovered without detriment. At the age of three she had measles of a virulent type, and was said to have been unconscious for fourteen days.

There was no pain or discharge from the ears in either illness, and at no time in the history of the case has there been any symptom pointing to suppuration in either tympanic cavity.

At about the age of three the child appeared to be deaf and had slowly become more so up to the present time. With the increasing deafness the power of uttering intelligible sounds had diminished until now the vocabulary was limited to a few sounds such as mammy, more and pease. The mother stated without being asked, that so deaf had the child become, that it was requisite to touch her to arouse her interest, unless the child previously was looking at the questioner. The Board school had refused her admission, the teachers at the convent school where she now attended had great difficulty in teaching her anything.

The father and mother and other children were possessed of good hearing and normal speech. The father had died recently of tuberculosis, and one child had died of the same disease. The family history was quite free from deaf mutism, nor were affections of the ear prevalent among the members of either parentage. The child herself appeared to be singularly bright, intelligent, and well formed, and of decidedly pleasing appearance. She was of normal height for her age, well nourished, and apparently without physical defects, other than those under investigation.

On being spoken to in a loud voice she answered no questions and did not utter a sound, but stared from the questioner to the mother, expressive of

inability to understand what was required of her. Noises made behind the child had no effect upon her, and no response was elicited by the bells of a repeater watch suddenly being struck close to the ear, whilst in the pocket of the observer. The pharynx was singularly free from disease, and the palate moved freely in response to the touch of a probe. The nose was well formed externally, but internally was considerably obstructed by two very large lower turbinal bodies. The external ear was well formed, but the auditory canal was rather long and unusual in its curve. It was curved forwards so that in looking into the ear the membrane would not be at once apparent. Some manipulation was requisite to get a view of the parts.

With some little difficulty a correct view was obtained, and in each ear, in contact with the membrane, was a hard, inspissated mass of cerumen of old standing. This was removed with some little difficulty. The membranes were found to be extremely retracted, somewhat opaque, but otherwise healthy. Politzer's bag was used, and a wash ordered for the nose, and the patient dismissed.

At our next interview the mother stated that the child apparently heard a good deal and had attempted to converse and make sounds to the other children resident in the house. It was quite apparent to me that the child could now hear sounds. The bells of the repeater watch when struck behind her produced a volte face of a most unmistakable character. On showing the child a small bronze lion she uttered the word, "dod," and on leaving the room said, when requested by the mother, "Goo bi." Since then the improvement has been quite remarkable, both in hearing and speech.

At the last interview the child repeated after the mother, whose lips were covered up, several verses of "Mary had a little lamb" more or less correctly and quite intelligibly. I have brought this case forward for your inspection and with it a few notes on deaf mutism that may refresh your memories on this singularly interesting and important subject.

DEAF MUTISM.

By the term deaf mute we are not to understand that the subject is totally deaf and totally dumb. A deaf mute is deaf in the ordinary acceptation of the term. He cannot hear so as to communicate by speech with his fellow creatures. A deaf mute is seldom stone deaf and absolutely dumb. Deaf mutism may be congenital or acquired. More than half the cases are acquired, and curiously enough, on the authority of Bezold, absolute deafness is more common in the acquired cases than in the congenital. About 60 per cent of deaf mutes have some hearing power. Many children classed as congenitally deaf hear to a greater or less degree, but not sufficiently to allow them to acquire the power of speech. Many cases born without defect of hearing, but who

(a) Abstract of Remarks made on exhibiting the patient before the British Laryngological Association, Friday, January 10th, 1902.

have lost the sense at an early age, are classed as congenitally deaf. The causes assigned to congenital deafness are consanguinity of marriage, hereditary transmission, and weak health from some constitutional dyscrasia on the part of the parents. Consanguineous marriages are only causative when joined by hereditary and other influences, as constitutional diseases. (L. Blanc).

Heredity exerts a great influence, especially in those families in which there are many cases of hardness of hearing, but direct transmission is absent. Mygind found that not a single child of deaf mute parents was itself deaf and dumb. (Randall). Acquired deaf mutism may be of two descriptions. Children who have lost their hearing after the acquisition of the power of speech, and children who have lost the hearing before the acquisition of the power of speech. The acquired variety of deaf mutism becomes apparent usually before the third year, but may develop as late as the sixth.

The pathological causal condition is almost invariably in the labyrinth. This may be confined, associated with, or supplemented by, or a sequela to pronounced virulent inflammation of the middle ear.

The labyrinthitis may be of two kinds, labyrinthitis hyperplastica and labyrinthitis exudativa. Of the hyperplastic variety the commonest cause is syphilis, congenital or acquired. The exudative variety is the commoner form, and is most frequently associated with, and the result of, one of the acute infectious diseases, such as measles, scarlet fever, diphtheria, and epidemic parotitis. It may supervene, however, quite suddenly, associated with a rigor as a complication of epidemic cerebro-spinal meningitis. We then get sometimes pain in the head, with delirium, stupor, or drowsiness.

The deafness is absolute, and is associated with tinnitus, vertigo and loss of co-ordination. If death does not take place most of these symptoms pass away in a few weeks, leaving the patient profoundly deaf, and his co-ordination impaired.

The prognosis in these cases is sometimes hopeful, as in the present case, when there has been no destruction of the contents or walls of the middle ear, always most unfavourable when such destruction has taken place.

In the two forms of labyrinthitis the exudative and hyperplastic, iodide of potassium, mercury and pilocarpine may be found useful associated with general treatment.

THE TREATMENT OF CONGENITAL DISPLACEMENT OF THE HIP-JOINTS.

By NOBLE SMITH, F.R.C.S.ED.,
Senior Surgeon, City Orthopaedic Hospital, &c.

WITH regard to diagnosis, the affection has to be distinguished from traumatic, paralytic, and spontaneous dislocations, some cases of coxitis, rachitic lordosis, coxa vara, and even bow legs, but the only affection which can be, as a rule, mistaken for this displacement by those having as much experience of it as the members of the Society is coxa vara, and the only certain way of forming a diagnosis is by means of the X-rays. I think I am expressing the generally received opinion in saying that the formidable operation of scooping out the imperfect acetabulum, and bringing down the head of the femur into such artificial depression by a wound which obviously opened up the joint, is not satisfactory, even if it be justifiable. After such an operation cases are known sometimes to relapse, ankylosis has

occasionally followed, and some deaths have taken place.

These operations have been chiefly tried by Continental surgeons, and I think that the results do not warrant the procedure.

Good results from treatment by continued extension of the affected limb, a plan of treatment advocated and practised years ago by Pravaz and carried out most carefully by Buckmaster Brown, and subsequently by William Adams have been recorded. Then we have the more forcible method of Paci, which has also been successful to a certain extent. If it may be said of all these plans that relapses occur, it must yet be acknowledged that the results are better than if the sufferers had remained without any treatment whatever.

More recently a bloodless operation has been carried out with which Lorenz's name is chiefly associated. This consists in forced extension, then flexion, rotation and abduction of the femur, with an endeavour to replace the head of the bone into its normal position, or at least into the place or neighbourhood of the socket. Then fixing the limb by plaster of Paris bandages in a strongly abducted position so as to make the head of the bone press firmly towards the pelvis with the intention of its forming by pressure a place for itself.

I have seen good results from this practice, but I doubt if it has any advantages over simple extension by means of a long Liston's splint, as used for a fractured thigh-bone. The perineal band draws the pelvis upwards, and the limb is drawn down and fixed to the splint in the ordinary way. I find that the head of the bone can either be brought down at once, or it may take several weeks before it will reach the natural position. After a certain period weights with a pulley may be substituted for the splint, or used alternately.

In some cases there is so much twist in the neck of the femur that when the head of the bone is placed in its normal position the feet would point inwards, and upon placing the feet straight forwards the head of the femur is dislocated anteriorly. This condition may necessitate osteotomy of the femur.

Some lateral pressure may be applied to the hip by a metal band after the bone had descended, but such lateral pressure should be applied with great caution in the case of girls, because we may easily compress the pelvic cavity, and as girls are more often affected by this displacement than boys, a serious narrowing of the pelvis would ensue.

This caution applies especially to Lorenz's bloodless method, for lateral pressure is a material part of his procedure.

In many cases, and especially in older children, the reduction of the deformity is impeded by contraction of muscles, especially the adductors and tensor vaginæ femoris.

All these contracted muscles may have to be divided or stretched before the reduction can be completed, and it is always desirable to ensure free abduction of the limbs. After keeping the head of the femur in its improved position for a few months, it will be found that the joint is becoming fixed in such position; that is to say, the tendency to rise upwards towards the crest of the ilium is lessened. It will probably require at least six or eight months to get sufficient firmness to resist a moderate pressure upwards, but it would be very unwise to allow a child to walk about with its body weight on this joint under eighteen months or two years. This does not, however, involve so long a period of absolute recumbency. The patient may, after the first six months or so, get about on crutches, with a raised sole on the sound limb, if only one joint is affected—or to ride on a tricycle or rocking-horse if both joints were deformed.

In some cases it has been found that a fold of the capsule is interposed between the head of the bone and the acetabulum, and under such circumstances there is some tendency to relapse, but firm lateral pressure will probably, in time, overcome this obstruction. One American surgeon, Bradford, of Boston, has stated that if at the end of a month the head of the femur does not seem sufficiently firm in its natural position an operation is necessary, but I do not think the time sufficient for a fair trial.

I am enabled to exhibit a number of skiagraphs and ordinary photographs showing different patients and the stages of treatment. These photographs and the notes of the cases show very good results with very little tendency to relapse. By such safe and comparatively simple procedures patients are ultimately able to walk about with little or no difficulty, and the very disfiguring deformity, the waddling gait and severe lordosis, which occur when no treatment is carried out, are generally after such treatment, much reduced or quite absent.

DIPHTHERIA. (a)

By FREDERICK S. PALMER, M.D., M.R.C.P.

President of Durham University Medical Graduates' Association.

It may be justly said that diphtheria is one of the severest scourges of humanity, attacking persons of all ages, in all climates, and at all seasons. It is pre-eminently a specific disease, caused, according to our present views of the subject, by an invasion of the bacillus diphtheriae, "complicated by the action or co-operation of other microbic organisms, and their toxins." The so-called specific bacillus was discovered by Klebs in 1883, and by Loeffler the following year. It is therefore commonly called the Klebs-Loeffler bacillus to retain both names. The nature and mode of action of the toxins are only partly known, but they are believed to be either enzymes, toxalbumens, or albumoses.

Hygienic Etiology.—In the majority of text-books, the period of incubation is given at from two to eight days, but it is probably shorter; or certainly well within these limits. The symptoms frequently appear in less than forty-eight hours after exposure to the contagion, and are seldom delayed beyond five or six days. The quarantine necessary to be observed after such an accident is ten days. The connection between diphtheria and a polluted water supply has so far, not been satisfactorily traced; although clinical observations point in that direction, and to other insanitary conditions, among which the following may be cited, dampness of soil, defective, or inadequate drainage, and scavenging, the disturbance of refuse heaps, and other causes of bad smells of a similar kind; also to the made soils on which newly-inhabited houses are built as contributory factors. The contagium may be distributed by the milk supply, or communicated by inoculation. Direct contact is by far the most common means of communication, but there can be no question that it is carried through the air, or by clothing, bedding, and other like agencies which have been in contact with the sick. The virus attaches itself with great tenacity to the room and its appointments. One attack is not protective. The incidence is greatest in children between two and twelve years of age, indeed the highest rate of mortality is seen in the very young. Females appear to be more liable to diphtheria than males. The herding, or congregating of children in the public elementary and other schools, plays an important part in the diffusion of the disease. The duration of infectivity is a matter of the deepest interest at the present moment. Bold is the man

who would venture to answer this question. Recent reports and statistics on this subject, based for the most part on the results of bacteriological examination are simply appalling. Several instances are recorded in which the organism has been found in the secretions of the throat and nose six months after an attack. (a) In one case reported by Golay, quoted by Osler, the presence of the bacillus was demonstrated 362 days after the commencement of the illness, and during that period the patient had three acute relapses. Recently, a case came under my notice, in which a culture made from a swab taken from a boy's throat five months after an attack, when he had been to all appearances perfectly well for a long time, killed a guinea-pig forty-eight hours after inoculation from virulent diphtheria. (b) The authorities who have expressed any opinion about the necessary quarantine for convalescents, insist on a period of at least forty-two days.

No other disease has claimed so many victims among physicians, nurses, and attendants on the sick. In the words of Niemeyer, "Science (c) has to mourn the loss of a series of excellent physicians and observers." Three such instances occur to my memory at the present moment. Two happened to young, and promising members of our profession, who in their heroic efforts to save lives sacrificed their own. No one of our generation will forget the sad lethal kiss of the beloved Princess Alice, Grand Duchess of Hesse, in 1878.

Semeiology.—In describing the symptoms of diphtheria, I shall adopt the excellent and comprehensive divisions of (d) Dr. F. Foord Caiger in his masterly article published in Allchin's "Manual of Medicine" last year. He arranges the various types of the disease under the following heads:—

1. The mild faucial form.
2. The severe faucial form usually showing a tendency to extension.
3. The laryngeal form.
4. The nasal form.
5. Other, and irregular forms.

The Mild Faucial Form is the type which presents the greatest difficulty in diagnosis. In the early stages of the affection there are in my experience no certain means by which it can be distinguished from an ordinary attack of lacunar or follicular amygdalitis, not even by bacteriological examination. It is commonly seen in adults, but it also occurs in children. It is ushered in by chilliness, headache, sometimes vomiting, sore throat, and discomfort in deglutition, followed by pyrexia and submaxillary tenderness. The temperature does not often rise above 101° or 102° Fahr. On inspection of the throat, one or perhaps both, tonsils are seen to be hyperæmic and swollen. On the surface one or more patches of white, or greyish white, exudate are noticed on the tonsils or uvula. When observed in the latter position I regard it as a point of great diagnostic value, in fact it is asserted that (e) "extension of the exudation to the soft palate, and uvula is pathognomonic of diphtheria as contrasted with lacunar tonsillitis." I would even go so far as to say that any patch of exudation first noticed on the uvula is almost a certain indication of its diphtheritic origin. There are swelling (added to the), tenderness of the glands, and frequently pain in the ear on the affected side. The exudation is generally loosely attached, and its margin defined. If there be no extension of the exudate the attack runs a short course of a few days (usually a week) when the throat clears, and convalescence begins.

(a) Abstract of Paper read at the Guthrie Society, Westminster Hospital.

The Severe Faucial Form is a disease of great gravity, and among young children, whom it principally attacks, the mortality is very high. It commences like many of the acute fevers with a rigor, vomiting, or possibly a convulsion, headache, general malaise, sore throat, and dysphagia, followed by febrile reaction; quite early the fauces, tonsils, and uvula are red and swollen. The tongue is coated with a thick, creamy fur, and there is marked depression from the first. In a few hours the temperature (which is never typical in diphtheria) may rise to 104° or more. The tonsils become so swollen that they appear to meet in the mesial line, and the uvula is frequently oedematous. Large patches of thick white, or dirty ashy grey membrane are observed on the tonsils, palatine arch, fauces, or uvula, which is sometimes completely ensheathed, so that its outlines cannot be distinguished. The exudation may spread to the pharynx, larynx, and trachea, or invade the nasal fossæ. In very severe cases I have seen the whole veil of the palate blocked up by deposit, and the fœtor of the patient's breath becomes horrible. An acrid discharge, thin, and sometimes blood-stained, trickles from the nares setting up soreness and irritation over the skin of the upper lip. There are tenderness, swelling, and frequently infiltration of the subcutaneous structures and glands in the submaxillary and cervical regions (Angina Ludovici) which may terminate in sloughing. Attempts to swallow liquid nourishment are followed by spluttering and regurgitation through the nose, the urine is very often albuminous, and the pulse small and feeble. As the case proceeds the distress and prostration increase, the colour of the exudate changes from putrefactive causes, and attempts at separation are commonly attended by a fresh formation; the face becomes livid and anxious, acts of deglutition are accompanied by acute pain, and hæmorrhages are not infrequent. If the membrane extends to the larynx all the horrors of croup become apparent. Even without this complication, life may be threatened from the virulence of the toxæmia, laryngeal spasm, or sudden collapse from acute cardiac failure—an event which may occur at any time during the course of the disease. In the more favourable cases, the swelling and hyperæmic condition of the parts gradually subside, the dirty discoloured exudate separates, and is cast off in the form of sloughs, leaving areas of superficial ulceration, which for the most part heal rapidly. It has on many occasions surprised me to note the small amount of permanent damage inflicted on the faucial structures after extensive exudations.

Laryngeal form.—There is much to be said in favour of Bretonneau's assertion that membranous croup is always secondary to some pharyngeal exudation. The advent of this form of diphtheria is announced by a small dry cough, coming on at intervals of varying duration, together with a marked alteration in the voice. Both these symptoms have a special character difficult to describe; but when once heard they are never forgotten. The cough is harsh, metallic, or barking; the voice hoarse or muffled in tone. A peculiar laryngo-tracheal or whistling sound is produced during inspiration. Several of these suffocative attacks occur during the day, but they are more apparent, and always worse at night. The child is restless, gets out of bed, and makes strenuous efforts to obtain air by the use of all his respiratory muscles. As the disease advances, the intervals of calm become shorter, the stridor is more permanent, the voice changes to a whisper, or, as Aretæus says (a) "*Vox nihil significat*." Soon there is no interval, the struggle for air becomes continuous, and is terrible to witness. There are retractions of

the epigastrium, intercostal spaces, and lower ribs, so well expressed by the words "sucking in." Desperate attempts are made by the sufferer to remove the obstruction. In his frenzy he clutches or tears at his throat, thrusts his fingers into his mouth, seizes any object within his grasp, and makes piteous appeals for assistance. The colour changes, the lips and finger ends become livid, the face purple, and if not promptly relieved by surgical measures, drowsiness, succeeded by coma deepening into the lethal state, closes the scene (a). In those cases which terminate favourably, casts of the trachea and bronchi more or less complete are expelled, and recovery may be rapid.

Nasal Form.—Membranous, or fibrinous rhinitis, in other words nasal diphtheria, is an affection not usually accompanied by marked constitutional disturbance. patches of exudate are seen in the nares, in conjunction with rhinorrhœa, producing (b) "soreness of the external nostrils, and some tenderness of the superficial lymphatic glands beneath the jaw." For the most part the disease runs a benign course, but it occasionally becomes chronic, and large flakes of membrane are cast off from time to time. It must not, however, be overlooked that nasal diphtheria sometimes, though not often, presents malignant characteristics, and may extend to the ear, lachrymal ducts, conjunctive, and antra. (c) "A question of great importance in relation to these cases is the duration of infectivity."

Other, or Irregular Types.—The latent or ambulant form is, I venture to think, much more common than is generally supposed. In this group the cases are nearly all of a mild character, so mild as to escape observation. There may be no suspicion of diphtheritic infection at the time, nor is the condition recognised unless laryngeal complications arise, or paralytic symptoms develop at a later time. (d) "Heubner, quoted by Osler, has discovered cases usually secondary, occurring chiefly in hospital practice in young persons, the subjects of wasting affections, such as rickets and tuberculosis."

Complications and Sequelæ.—(e) In the medical supplement to the fourteenth annual report of the Metropolitan Asylums Board published not long ago, the following statistics are given, showing the incidence of complications occurring among 8,310 cases of diphtheria which were under treatment in the twelve fever hospitals during 1899. These figures have been supplied to me by Dr. Voelcker, of the Children's Hospital, Great Ormond Street, to whom I am much indebted for very valuable information and kind help.

Albuminuria	...	37	per cent.
Post-diphtheritic paralysis	205	"	
Relapse	...	2	"
Broncho-pneumonia	...	12	"
Otitis media	...	6	"
Lobar pneumonia	...	2	"
Nephritis	...	0.6	"
Scarlatina	...	4.3	"
Varicella	...	1	"

And in less than 1 per cent. with measles, whooping cough, German measles, tuberculosis, enteric fever, erysipelas, and parotitis. The other complications are hæmorrhages, skin rashes, spasm of the glottis, and the ever present risk of cardiac syncope. Hæmorrhages may arise from any mucous surface, such as epistaxis and the like, from the necrotic process involved in the separation of sloughs or as purpura. They are of evil augury; such cases do not usually recover. The exanthems seen are urticaria, diffuse

erythema, and an anomalous rash resembling morbilli after the antitoxin treatment. (a) Two cases of acute relapse have been seen at the isolation block of the Children's Hospital within the last two years. Although albuminuria is by far the most constant of the complications, true nephritis is rare. It may be suspected if the amount of albumen be large. As a rule it tends to recovery. (b) In addition to the lobar and broncho-pneumonia given in the report, areas of collapse occur, and in very severe cases gangrene of the lung. Like the other acute infectious diseases, diphtheria is occasionally complicated with hemiplegia and other forms of palsy, the results of embolism, thrombosis, or hæmorrhage. Sudden collapse from cardiac syncope is the gravest of the complications. It may occur at any time either during or after an attack until convalescence is thoroughly established, but is most common during the second week. (c) The warning signs are a rapid fall in temperature, slow irregular pulse with diminished tension, increasing prostration, great restlessness, coldness of the extremities, præcordial or violent epigastric pain, continuous vomiting, great pallor of the face, blueness of the lips, sighing, irregular respiration, and muscular cramps.

Post-diphtheritic multiple neuritis is always a sequel, not a complication. (d) According to Dr. Voelcker, "insufficient food and inefficient nursing are predisposing causes." It occurs with the greatest frequency during the second or third week, but it has been seen in exceptional cases as late as the sixth or seventh. It may follow any form of diphtheritic infection, mild or severe. (e) The laryngeal and nasal types appear to be much less frequently pursued by neuritis than the faucial forms. There is no doubt that this sequel is most commonly noticed after severe attacks; opinions differ considerably regarding its relative proportion in children and adults. I am inclined to agree with Dr. Caiger that it is more often seen in children. (f) The first indications are irregularity and feebleness of pulse (not tachycardia), most noticeable in the early morning hours, a tendency to cough and splutter when fed, from involvement of the laryngeal muscles, and food finding its way into the larynx, nasal phonation, the velum hangs motionless: most commonly bilaterally, it is sensitive to the touch, and its reflex is lost, food regurgitates through the nose. The ocular symptoms observed are indistinctness of vision, failure of accommodation for near objects from paralysis of the ciliary muscle (cycloplegia), strabismus. The external rectus is most frequently attacked, then the internal rectus and superior oblique, diplopia, and ptosis are less common, weakness and sensory disturbance of the legs with lassitude, tingling, and ataxic gait, sometimes the arms are affected. The knee-jerks (at first frequently exaggerated) are lost early, and may not reappear for six months or more. In fatal cases the paralysis extends to the trunk involving the intercostals and diaphragm and may cause pulmonary collapse and pneumonia. The immediate cause of death in these severe forms of neuritis, is respiratory, and cardiac failure from toxins acting on the central nervous system.

The distribution of the neuritis is very variable. It is seen quite as often after the special antitoxin treatment as in those which have not had the serum. The paralysis in the extremities is seldom complete, except it be in very severe attacks. (g) "Palsy of

one or more of the cranial nerves is liable to occur and to become permanent, due probably to acute inflammation of their nuclei." With the view of determining the order of precedence of these nervous systems (a) Goodall analysed the result of 125 cases. He found paralysis of the palate was noticed first in 83, the ciliary muscles in 20, palate and ciliary muscles in 5, palate and lower extremities in 4, lower extremities in 3, muscles of the pharynx in 2, muscles of respiration in 2. In the remaining 6, the parts first affected were scattered. (b) When the limbs are involved, the muscles soon atrophy, and the reaction of degeneration is obtained. The ratio may be roughly represented at about one in four or five of the cases according to the latest returns. Roger, who made a careful study of the incidence at the Hôpital des Enfants in Paris thirty years ago, placed it at one in every three or four. I entirely agree in Dr. Voelcker's opinion that this paralytic sequel is a serious affection, one not to be lightly regarded, and one which not seldom terminates in the exit lethalis.

Differential Diagnosis.—The early recognition of diphtheritic infection is a matter of supreme importance. I know of no disease which has taxed my power of observation more severely, none in which I have been so frequently mistaken, even after years of experience; bacteriological examination as a positive test is not only uncertain in its result, but actually in some instances misleading. It is, I think, to clinical observation, supplemented by bacteriological confirmation, that we may look for a solution of the difficulty. For many years past I have been accustomed to regard the majority of sore throats met with in practice as infective, demanding at least a few days isolation, and antiseptic treatment. I have systematically adopted this plan, particularly in schools, where an error in diagnosis is not infrequently followed by wide-spread mischief. The points which guide one in arriving at a diagnosis of diphtheria are patches of exudation on the uvula, palate, or fauces which tend to coalesce. Albuminuria, marked depression, in undue proportion to the severity of the symptoms, tenderness of the glands, a temperature not much raised, the age and sex of the patient, the season, the presence of any nasal, or ear discharge, or any other illness in the house. An inquiry should be made into the sanitary surroundings, the milk supply, whether the patient has been exposed to any known source of infection in visiting friends, or has been present at any place of entertainment within the recognised period of incubation. Such evidences will, in the majority of instances, help us to distinguish a diphtheria angina from an attack of lacunar tonsillitis. In scarlatina, the faucial mucous membrane is tumid and vividly red, the tongue clean, or strawberry-like in appearance, the temperature high, vomiting is a frequent symptom in the early stages, and the punctiform rash is not long delayed. The neuritis has to be distinguished from other forms of toxic multiple neuritis, alcoholic lead and arsenical neuritis, anterior poliomyelitis, tabes, and hysteria. The diagnostic signs to be borne in mind, are the history, irregular distribution of the palsy, absence of knee-jerks, nasal phonation, paralysis of the palate, and ocular disturbances.

An epidemic of small-pox is reported to have broken out in Nice, but in the absence of non-enforcement of any system of compulsory notification it is impossible to make any definite statement, satisfactory or otherwise.

SOME ABNORMALITIES AND COMPLICATIONS
IN A
MIDWIFERY PRACTICE
EXTENDING OVER THIRTEEN YEARS.

By M. CHARLES O'GORMAN, L.M.R.C.S.,
K. & Q.R.C.P.I.,

Medical Officer of Health for Aughrim, co. Wicklow.

It is admitted by all that emergencies and difficulties arise more frequently in the practice of midwifery than in any other branch of the medical profession. Experience reveals many points of value, and as I have for the last thirteen years carefully collected notes on my cases (over 400 in all), I take the opportunity of relating those which may be looked on as abnormal and of interest.

I do not intend to touch on ordinary labour cases, or those in which the forceps have been requisitioned, but to give a synopsis of the following:—

IMPERFORATE ANUS.

Mrs. H., *æt.* 34, was delivered of a male child on May 19th, 1892. On the 23rd the husband of the woman came to me and said the baby's bowels had not moved, that oil had been administered but without effect. On my arriving at the house I met Dr. Satchwell, who informed me that it was a case of "imperforate anus." I examined the baby, then four days old, and although it cried lustily no bulging of the perineum was perceptible; the abdomen was hard and swollen and seemingly tender to the touch. There was no vomiting.

Having consulted, we (Dr. Satchwell and myself) agreed to operate. I did a perineal section, keeping close to the coccyx, but could find no bowel.

The little patient became very exhausted, and not having passed water for over eight hours I passed a No. 1 catheter. A most foul smell of intestinal gas escaped immediately, but no urine. On withdrawing the catheter the eye was plugged with fecal matter. The case was now clear that the bowel opened into the bladder. We then made an opening in the groin (Littre's), and, having secured the intestine, dressed it antiseptically, as also the perineum. Small quantities of feces passed, some hours after, and also urine. The infant lived for four days. What a pity the malformation was not discovered at birth, but such anomalies will pass unobserved by the handy-woman.

"RETAINED PLACENTA."

I attended Mrs. D., *æt.* 41, a multipara, on July 27th, 1893. The baby was born early that morning, and I arrived at the patient's house about 11 p.m. Mrs. D. informed me that the after-birth had always to be removed manually.

Pressure over the uterus revealed the fact that the placenta was in utero.

I introduced my hand, and having grasped the placenta began traction, and this I continued for fully half-an-hour. There was good uterine contraction, but the placental adhesion was extraordinary. Suddenly my hand was forcibly expelled, and with it the greater part of the placenta. I again inserted my hand, and with my nails literally scraped away the remaining placenta, which, by the way, was situated at the fundus uteri.

Examining the placenta, I found it tough, and passing through it strings or tendons as thick and strong as the tendons of a turkey's leg. These string-like tendons were the cause of the retention. A fetid discharge lasted, off and on, for nearly three months, but proved of little inconvenience to the patient, who syringed (antiseptically) daily.

I attended Mrs. D. on August 18th, 1894, and the same difficulty presented itself, but I curetted the uterus on the fourth day, and the patient resumed her ordinary work on the thirteenth.

"ACCIDENTAL HÆMORRHAGE."

Some cases of accidental hæmorrhage have occurred in my practice from time to time, but a case I attended

on the morning of January 26th, 1896, seems to me sufficiently interesting for publication.

Mrs. G., *æt.* 40, a multipara, in the seventh month of pregnancy, was taken suddenly ill under the following circumstances:—

Her maid servant left her early on the morning of January 25th, and consequently she had to do some additional household work. She (*i.e.*, Mrs. G.) carried on several occasions two buckets of water, one in each hand, a very considerable distance and milked five cows. She retired to rest at eleven o'clock that night feeling quite well, and slept until 12.30, when she awoke in great pain and an intense desire to pass water. She arose for that purpose, but to her surprise began to bleed copiously. The ordinary bed-chamber became full of blood; she fainted, and was lifted into bed. When I arrived (about 5.30 a.m.) the hæmorrhage had saturated through everything on the bed and the patient was completely collapsed. I immediately made a vaginal examination. The os was high up, undilated, and frequent gusts of hæmorrhage ensued. The patient moaned frequently, and complained of intermittent pains in the vagina. *Ballottement* was easily felt, and a head presentation. External auscultation revealed nothing. No foetal heart, no placental bruit. I diagnosed accidental hæmorrhage from the above mentioned symptoms.

Treatment.—By means of an irrigator I injected into the vagina, streams of hot and cold water alternately, gave a full dose of ergot, and applied a tight abdominal binder. In half an hour the hæmorrhage ceased, the patient dozed, and about an hour later labour pains came on. From time to time I made careful vaginal examinations. Finally I ruptured the membranes, and the labour terminated normally with these exceptions *viz.*, the fœtus, with umbilical cord and placenta were expelled simultaneously. The placenta was small and bloodless. On cutting the cord it contained no blood, the fœtus though well developed, was anæmic to a degree, and dead, I should say for hours. Quantities of large blood clots were also expelled.

This case is an excellent sample of complete separation of the placenta, due in all probability to the woman carrying the buckets of water, an exercise which causes a great bearing-down, and a danger to all during gestation.

ALBUMINURIA AND PREGNANCY.

In May, 1893, I was consulted by Mrs. B., *æt.* 30, a multipara. She was in the eighth month of pregnancy, abnormally large, pulse 100, distressing dyspnoea, cardiac palpitation, anasarca, and greatly depressed. Her first words were, "Doctor, I am dying; save my child." To acquiesce then to such a gloomy view of her case I considered would do no good, so I replied, "Oh, nonsense, I can save you and the baby."

I made a few suggestions, *viz.*, to elevate the feet, absolute rest in the prone position (which proved difficult on account of the dyspnoea), a milk diet only. I secured a sample of urine, and promised to return in the evening.

I carefully examined the urine, and found it full of albumen.

I visited the patient again at 9 p.m. She was propped up with pillows, and presented the same symptoms as already described. The foetal heart and placental bruit were audible on auscultation, vaginal examination revealed nothing unusual, but the vulvæ were very cedematous. These I punctured, also the legs, giving much relief.

I prescribed hydrate chloral (*gr.* x) in water three times a day, and a mixture containing digitalis, *spt.* ether *nit.*, *tinct.* nux vomica, and chloroform water. The loins were cupped, and poultices applied every two hours.

I explained to her friends her critical condition, and the complications which might occur during or after labour, and I suggested bringing on labour if improvement did not show itself, but to such treatment they would not consent. The patient got a good night (the first for many weeks), and next day she said she felt greatly relieved.

Symptoms varied, one day the patient felt better and

cheerful, at other times the headache, palpitations, and dyspnoea caused much distress. The urine became very scanty, and if possible, more albuminous. Her appearance changed, the face becoming puffed and "pasty."

On June 26th, 1893, she was confined, after five hours labour, of a male child, and I left both well, but next day my patient complained of intense headache, and spoke incoherently. I had the baby weaned, and added bromide potash to the hydrate chloral. She had a "fit" that evening, lasting about an hour. The loins were again cupped and poulticed.

About the fifth day the dropsy had diminished so much that very little "pitting" on pressure existed. On July 7th (eleventh day after confinement), the patient, when sitting up in bed, had a smart hæmorrhage, which ceased on lying down. Her appetite now improved, and nearly all oedema passed away. Headache was the chief trouble.

On September 21st, at 8 o'clock, p.m., the baby, who up to then was apparently quite well, got a fit of convulsions, and died the next day. This unlooked-for event naturally told on the mother, so shortly afterwards I ordered her change of air, which she took.

She then passed out of my care, but her subsequent history was this: She became pregnant again in February, 1894, premature labour had to be induced in the last week of May, she became practically blind, and died of oedema of the glottis. This case fully exemplifies the views of Playfair, who says:—"We are scarcely in possession of a sufficiently large number of observations to justify any very accurate conclusions as to the risk attending albuminuria during pregnancy," and again, Hfmeir believes the same is a severe complication for mother and child.

TUMOUR OBSTRUCTING LABOUR.

On March 26th, 1898, I attended a Mrs. K., æt. 45, a primipara. She was in labour for six hours, and was bleeding freely. On making a vaginal examination a large mass was felt, filling the posterior cul-de-sac, the head was presenting, and the membranes intact. I immediately ruptured the membranes, and endeavoured to push back the tumour, which I succeeded in doing with difficulty. I then applied the forceps, and delivered quickly a male child.

Profuse hæmorrhage set in, so I manually removed the placenta, injected hypodermically ergot, and douched with hot saline solution. The bleeding ceased, and the patient had some brandy. I applied a binder, &c.

The pulse was now barely perceptible and the respirations quick, so elevating the lower end of the bed I let the patient rest before seeking for the tumour. At the expiration of two hours (that is five altogether since delivery) she complained of great bearing down pains, so I made a vaginal exploration. The tumour had again occupied the vagina posteriorly, and a pedicle could be traced for an inch, ending about the same length within the uterus. I seized the pedicle with a long catch-forceps, and having twisted it, removed the tumour. Examination then was unsatisfactory, for a small piece of pedicle was still adherent to the lower zone of uterus. This I curetted, but had to abandon before complete on account of hæmorrhage.

Next day Dr. Alfred Smith was summoned in consultation.

Before his arrival an unfortunate accident happened. The baby was sent to be christened. A strong wind was blowing, and it was bitterly cold, and on arriving at the chapel the infant was dead. A woman, no doubt actuated with good, but imprudent, intentions, ran into the bedroom of Mrs. K. and told her. This shock produced a dreadful flooding, and I was hurriedly summoned. I succeeded in arresting it.

On Dr. Smith arriving I gave chloroform, and the uterus being drawn down, Dr. Smith removed the remaining piece of pedicle and injected iodine. An astringent mixture and stimulants were prescribed.

An hour after the shiverings which follow iodine injection came on, and were constant during the night. Next day the patient presented a dreadful appearance. She was deadly pale, quick respirations, thready pulse, tongue coated, and over the whole cardiac region a loud

systolic bruit. There was no bleeding, although great restlessness. This condition lasted for another day and night, when she died.

Prognosis in this case could have been nothing but exceedingly grave from the start, but the hæmorrhages, age of patient, the shocks, particularly extracting the tumour, left the case as one inevitably beyond recovery.

SEPTIC HETEROGENETIC POISONING.

I attended a most interesting case on April 17th, 1895. The history of it is this: Mrs. K., æt. 24, a multipara, consulted me a fortnight before her confinement regarding a painful *tendinous paronychia* on the index finger of the right hand. I lanced it, and in five days it was well. Her husband, a sea captain, returned home from a voyage. He always suffered from suppurating cervical glands; in fact, his whole neck was riddled with holes from which oozed pus of an offensive kind.

Mrs. K.'s confinement passed off normally. On visiting her the next day she was sitting up in bed dressing (with lint and carbolic oil, the suppurating glands on her husband's neck. I remonstrated with both, and pointed out the deadly danger she was exposing herself to by such a proceeding, and inspected there and then a perfect cleansing and disinfection of her hands. On visiting two days later I found the index finger, the seat of the paronychia, very painful, red and enlarged. Mrs. K. complained of headache and shiverings, her face was flushed, pulse 110, temperature 102°. The breasts were full, and the right axillary glands enlarged and tender. The glands of the groin were also affected. The nurse informed me that my orders were not carried out by my patient, and furthermore that the husband had absolutely slept in the bed with her and the baby for the two previous nights.

I had the finger leached and poulticed (boracic). Gave quinine in doses of gr. x every three hours. Exhausted the breasts of milk, weaned the baby, and applied belladonna ointment to all other infected glands. Beef tea and milk ordered in large quantities.

In spite of every precaution, nourishment, change of room, antiseptics, good nursing, the glands suppurated one after another, and finally, on the fifteenth day, the patient succumbed.

PRESENTATION OF THE ARM AND TRUNK.—PODALIC VERSION.

I was asked by Dr. C. E. R. Gardiner to see a patient (Mrs. N.) on April 30th, 1898. When I arrived the patient was under chloroform (Mr. Howard). I examined the case, and whilst doing so an arm came through the vagina. The membranes had been ruptured for four or five hours, and the uterus was strongly contracted. I endeavoured to pass up my hand, but could not. Dr. Gardiner tried and also failed. As the patient was now under chloroform for two hours, I suggested letting her have a rest, and to inject morphia, $\frac{1}{2}$ gr., into the hip. My reason for this suggestion was to lessen, if possible, the contraction of the uterus and stay the frequent pains. This was agreed to. After the lapse of an hour we again gave chloroform, and Dr. Gardiner amputated the presenting arm and found no difficulty in passing the hand along the back of the child, seizing the legs, and terminating labour. The patient made an uninterrupted recovery.

MULTIPLE PREGNANCIES.

My principal cases of multiple pregnancies are as follows:—

1. Mrs. W., confined June 20th, 1897, two females. Presentation, heads.
2. Mrs. M., confined April 16th, 1897, male and female. Presentation, head and breech.
3. Mrs. McD., confined April 17th, 1897, male and female. Presentation, head and breech.
4. Mrs. M., confined June 16th, 1897, male and female. Presentation, both breech.
5. Mrs. K., confined May 3rd, 1899, two males and one female. Head, breech, head.
6. Mrs. P., confined February 24th, 1900, two females. Presentation, head and breech.

Remarks—In Cases Nos. 3 and 6 there was but one placenta, and as you see in No. 3 the sex differed, and in No. 6 was the same. Schroeder says that in such a case the twins must have been developed from a single ovule containing a double germ, and in this he is opposed by Dr. Brunton's theory. I consider that in all probability two placentae existed at one time, and became, as pregnancy advanced, fused into a single mass.

Case No. 5, triplets, is of great interest. The male twins had a common placenta, but the female had a separate one. The males were very nearly full time, but the female was barely four months. This case proves that it is possible for *superfœtation* to occur at a far advanced existing pregnancy.

Clinical Record.

A CASE OF DIABETES MELLITUS WITH DISAPPEARANCE OF SUGAR UNDER THE TALLERMAN SUPERHEATED AIR TREATMENT.

By DAVID WALSH, M.D., Edin.,
Physician, Western Skin Hospital, London, W.

THE treatment of glycosuric diabetes is a matter of such great importance in practical medicine that there need be no apology in relating the following experience:—The patient, a Wesleyan Methodist minister, thirty years of age, had been under medical care for the disease mentioned for about two years. His treatment consisted mainly in diet and in the administration of codeia pills. The disease, however, was not arrested, and the patient's condition had grown steadily worse. When first seen by the present writer in January, 1901, he was passing three pints of urine daily, with a percentage on January 19th, as ascertained by a personal analysis, of 2.5 sugar. He underwent several courses of the Tallerman superheated air treatment, and from the outset experienced an immediate improvement in health. Most of the subsequent analyses registering the excretion of sugar were made in the country by Mr. A. M. Hudson, M.P.S., a chemist at Cranbrook, who estimated the amount by Fehling's solution and by Roberts' fermentation test.

Treatment by superheated air commenced on January 25th, 1901, and twelve exposures were made ending February 22nd, 1901. After an interval of two months treatment was again continued from April 25th, 1901, to May 24th, eleven exposures. From the following table it will be seen that the improvement shown after the first month's treatment, ending February 22nd, was kept up between that date and April 25th, although the superheated air treatment was suspended during the latter interval. This continuous decrease in the excretion of sugar is a remarkable and noteworthy feature of the case. The urinary excretion of fluid and of sugar was as follows:—

1901.	Amount.	Sp. Gr.	Grammes per oz.	Per cent. of sugar.
Jan. 19 ...	60 ...	1035 ...	— ...	2.5
Feb. 25 ...	50 ...	1032 ...	.64 ...	2.1
March 4 ...	51 ...	1030 ...	.48 ...	1.66
" 11 ...	52 ...	1030 ...	.34 ...	1.19
" 18 ...	51 ...	1030 ...	.32 ...	1.18
" 25 ...	51 ...	1030 ...	.31 ...	1.09
April 1 ...	42 ...	1032 ...	.38 ...	1.18
" 8 ...	54 ...	1024 ...	.24 ...	.84
" 15 ...	62 ...	1024 ...	.21 ...	.71
June and July report from country, "scarcely a trace."				

When the patient first came under observation he complained of frontal headaches, constipation, insomnia, and general nervous and bodily debility. His health improved considerably by the end of the first course (nine treatments), and at the end of the second course (twenty-three treatments) the patient said he felt "practically well." So great was the improvement that a certificate was granted him of fitness to undertake a laborious country ministerial charge in Cornwall. There he has remained until quite recently, when there has been some return of the complaint. A provincial chemist (Mr. T. Farnsworth, Codnor, near Derby) re-

ported "scarcely a trace" of sugar in the urine in June and in July, 1901.

In the foregoing we have evidently had to deal with a chronic case of glycosuria. The practical cure that has been effected must be attributed to the Tallerman superheated air treatment, as that was the main additional and concurrent therapeutic circumstance in the case. In spite of the recurrence to a limited extent of the sugar, the fact still remains that a patient who for two years had been in a progressive state of debility was restored to such a condition of general bodily health that he was able to undertake the duties of a laborious occupation. It is of course impossible to arrive at trustworthy conclusions on the strength of a single case, and every one knows that sugar has disappeared from the urine while the patient has taken certain drugs, as, for instance, boracic acid, but such a result has not been constant. At the same time the facts of the superheated air case are most interesting, and seem to indicate that some forms of diabetes mellitus may be amenable to therapeutic measures which have already achieved in other directions results unattainable by drugs. In the present instance it should be mentioned that the special diabetic diet was maintained throughout the superheated air treatment. Diet, however, had failed to arrest the malady in the two years preceding the Tallerman treatment, which may fairly be credited with the highly satisfactory result. This special therapeutic method is well worthy of trial in other cases of glycosuria.

NOTES OF CASE.

W. B., æt. 30, Nonconformist preacher, came for advice January 19th, 1901. He complained of general debility; pain in back and legs when "run down"; liability to cold, &c.

He was pale, but stoutly built and muscles fairly firm. His father was alive and healthy at 80; his mother 68, dyspeptic but otherwise healthy. His eldest brother, who suffered from "spinal trouble," was 40 years of age, and had been treated at one time for muscular rheumatism. One sister died at eight months of age.

Personally the patient had never been vigorous. He had suffered from bowel attacks, griping pains, constipation with alternate attacks of diarrhoea, especially during the last year or two. At sixteen years of age he had a "touch of pleurisy," and spat blood many years ago. He had not lost weight during last 12 months and weighed 12 stone at time of examination. For two years he had been under treatment by various medical men at Hayward's Heath, Liverpool, &c., for sugar in the urine, and had been taking special diet. The latter comprised "Manhu" bread, green vegetables, meat, special wheats and other diabetic foods. The patient suffered from dyspepsia and chronic constipation, appetite moderate, thirst normal, lungs normal. No heart murmurs; pulse medium strength, regular; is anæmic and loses breath. He passed more urine than normal, but the quantity never at any time exceeded three pints in a day. Analysis showed sp. gr. 1035, with 2.5 per cent. of sugar in three pints of urine; no albumin. He complained of frontal headaches, from which he had always suffered more or less. He suffered much from insomnia, and lately his memory had failed a little. Special senses unaffected. Sometimes a feeling of "pins and needles" in hands and feet. Knee-jerks exaggerated. Pupils react to light and accommodation. Patient had been taking codeia pills for two years.

January 30th.—Patient felt some improvement after the third treatment. On February 13th the general condition was much improved and patient reported himself as sleeping well at home in the country but not in London. The urine was loaded with lithates, which had not been seen previously. On February 20th he had passed 48 ounces urine in the last twenty-four hours. Two days ago he passed two pints of urine, which he described as "very thick."

May 3rd.—Patient feels stronger and better in every way. Sleeps well. Certificate granted of ability to undertake a country charge as a Primitive Methodist in a country district in Cornwall.

On November 28th, 1901, patient reported some return of symptoms. Examination of urine shows sp. gr. 1018; sugar, 5 per cent. He reports 41 ozs. urine in a day.

He has since come up to London to undergo further treatment at the Welbeck Street Institute. He at once improved in general health, and the amount of sugar is steadily diminishing.

Remarks—Here we have a patient who for two years suffered from well-marked diabetes which had grown steadily worse in spite of ordinary treatment by diet and drugs. The sugar practically disappeared from the urine after several courses of the Tallerman superheated air treatment. At the same time his health, which had entirely broken down, was restored to such a pitch that he was able to undertake a laborious employment. It is true that under the stress of work the sugar has re-appeared to a modified degree, but the relief has nevertheless been notable. The case suggests most hopeful possibilities in the treatment of a disease that in the majority of cases has been hitherto regarded as incurable. Other observations on glycosuric patients have shown a marked diminution of sugar, notably one patient treated by the Tallerman method so long ago as 1897, when the sugar diminished rapidly in amount. The case described in the present article is now published, perhaps a little prematurely, in order that the credit of the special treatment in diabetes may remain in England, where the superheated air treatment was invented. Experience has shown that many of the investigations of English medical men have been "rediscovered" and published as original observations by physicians and surgeons both in America and on the Continent, more especially in Germany.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.
MEETING HELD FRIDAY, JAN. 10TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

MR. MAYO ROBSON (Leeds) read a paper on
THE RADICAL TREATMENT OF CHRONIC INTESTINAL
TUBERCULOSIS,

in which he observed that whatever might be their views regarding the treatment of acute intestinal ulceration, surgical treatment was generally advisable in chronic intestinal tuberculosis. He related seven cases (one male, six females) in which he had operated with only one death, and remarked that while in cases one and seven the adhesions to adjoining parts were very intimate, in the other cases the affected part of the bowel was quite free, thus rendering operative measures easy and simple. In cases one, two, three and five, his decalcified bone bobbin was employed as a temporary splint over which to apply sutures, a method which he had described on numerous occasions and which he still employed and advocated as being simple and efficient. The physiological rest to the diseased parts secured by short-circuiting, as in case three, and by colotomy in case six, seemed to answer so well that where the radical operation of excision involved serious difficulties or the patient was not in a condition to bear it, he would not hesitate in future to be content with similar procedures, and then to trust to general treatment and hygienic surroundings to assist in the cure. If in the future operative treatment should be thought advisable in acute cases he anticipated that short-circuiting the diseased area would be found to be the more useful procedure, as it was the easier and safer method to pursue, but experience alone would show whether his suggestions would prove of as much service in acute as they are in chronic cases. It was interesting to note that in cases one and seven where there were tuberculous nodules in the peritoneum, where, in fact, there was tuberculous peritonitis co-existent with the bowel disease, the mere exploratory operation had not cured or even arrested the tuberculous process, but that the

radical operation of removing the principal focus of disease, or, as in case three, the short-circuiting and so setting at rest the diseased bowel, was in all three cases effectual in putting a stop to the tuberculous peritonitis and, so far as one could see without the parts being exposed, in curing the more diffuse disease. All surgeons present must have had the experience of curing tuberculous peritonitis by simple abdominal section, with or without drainage, and probably many of them had also experienced disappointment in other cases where the diffusion had returned after a longer or shorter interval. He suggested that the explanation of these recurrent cases lay in the fact that the original focus of disease in the ovaries, Fallopian tubes, or bowel, had not been removed and had again been the starting point for a further diffusion of the tubercle throughout the peritoneal cavity. If that were the correct explanation the remedy was quite clear, viz., that wherever the original disease might be it should be removed if that were possible without adding seriously to the risk of operation.

Dr. EWART asked what were the earlier symptoms and in what the indications for operation consisted? He also asked whether tuberculin had been used?

Mr. CHARTERS SYMONDS thought operation was resorted to rather for the relief of obstruction than to cure the ulceration, and he related the case of a girl with symptoms of mild appendicitis for which the appendix had been removed, followed by a fecal fistula, in whom the cæcum was excised, when tuberculous ulceration of the intestine was found. He also mentioned two cases, possibly of tuberculous ulceration, in men. In one case of very long standing two feet of greatly distended intestine were excised. In the other the gut was short-circuited. He approved the idea of removing the focus of disease whenever possible.

Mr. WATSON CHEYNE mentioned the case of an infant with obstruction associated with extensive tuberculous disease of the peritoneum in which he short-circuited the intestine, and this was followed by recovery. Short-circuiting, he said, was sound practice, but it was open to question whether it was advisable to search for and remove the original focus of disease, though if this were strictly localised it might be well to do so. He thought this procedure was not advisable in diffuse tuberculous peritonitis in view of the patient's depressed condition.

Dr. NEWTON PITT agreed that in most cases operation was done more in view of the obstruction than of the ulceration. Tuberculous appendicitis, he thought, was decidedly rare.

Mr. BARKER said he had removed tuberculous masses from the abdomen of a small girl in the region of the appendix, with recovery. He deprecated interference in cases of matting together of the parts as this was likely to be followed by distressing fecal fistula. The most suitable cases for operation were those in which there was a considerable quantity of fluid. He agreed that tuberculous disease of the appendix was rare. He referred to a case in which the cæcum, the ascending, transverse and descending colon had been successfully removed for tuberculous ulceration, the patient recovering health and strength.

Mr. KEETLEY divided the cases into three classes (1) those in which, a tumour could be felt (glandular); (2) tuberculous appendicitis and (3), diffuse tuberculous peritonitis. He mentioned a case in which he had removed some glands from the mesentery, and urged that these should always be searched for and removed.

Dr. NORMAN DALTON mentioned the case of a girl, æt. 12, who presented symptoms of appendicitis in whom, on opening the abdomen, the peritoneum was seen to be thickly studded with tubercle. She made a good recovery.

Dr. PERCY KIDD insisted on the difficulty of diagnosing ulceration in the early stages and suggested that in most of these cases there was concomitant disease of the lungs. Multiple ulcers were more frequently met with in the cæcum than in the ileum, and he expressed surprise that tuberculous disease of the appendix was not more common than it was.

Mr. MAYO ROBSON, in reply, said that five out of three hundred cases of appendicitis on which he had

operated proved to be tuberculous. He thought that loss of flesh, abdominal pain, diarrhoea and night sweats were the symptoms on which one would rely, and he insisted on the importance of removing the focus of the disease whenever possible.

Dr. E. PERCY PATON on a case of

HAIR-BALL IN THE STOMACH OF A CHILD OF NINE,
SUCCESSFULLY REMOVED.

The case was that of an intelligent girl, *æt.* 9, in whom a lump was accidentally found in the epigastric region. As she was known to have eaten hair and other similar substances since she was three years old, and had only been broken of the habit recently, a hair-ball was diagnosed. There were no gastric symptoms. On opening the stomach a mass, consisting chiefly of the child's own hair, seven inches long, weighing seven and a quarter ounces, and having the general shape of the stomach, was extracted. The child recovered without a bad symptom.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, JAN. 2ND, 1902.

Dr. D. B. LEES, the President, in the Chair.

Mr. A. D. REID showed a girl, *æt.* 8, with

CONGENITAL SHORTENING OF THE RIGHT LOWER
EXTREMITY.

She was the third child, and the labour was normal and easy. There was no family history of importance, and no history of injury. The shortening was noticed soon after birth. The present measurements from the anterior superior iliac spine to the internal malleolus showed an inch and a half shortening of the right side. The shortening was in the thigh. The tip of the great trochanter was on both sides in its normal relation to Nélaton's line. There was no wasting of the limb and no limitation of movement, no disability, and there has never been any pain. Some compensatory lateral curvature of the spine had resulted. Skiagrams showed that the neck of the right femur was set at a much less obtuse angle to the shaft than on the left side, thus accounting for the shortening.

CASE OF DOUBTFUL CEREBRAL DISEASE.

Mr. F. JAFFREY showed a boy, *æt.* 7, whom he had trephined for doubtful cerebral disease. The boy had been admitted into the Belgrave Hospital for Children on July 29th, 1901, under the care of Dr. Cauley, having been taken ill suddenly three days before with severe headache and screaming. There was a doubtful history of a blow on the head. The weather was very hot, but nothing in the history definitely suggested heat stroke. On admission the boy was drowsy, irritable, stupid, and took little interest in anything. The head was a little retracted, and the knee jerks were exaggerated. There was no optic neuritis and no evidence of ear disease. On August 1st he developed severe convulsions, which were most marked in the arm, leg, and face on the right side. The eyes were staring and consciousness was abolished. On the following morning Mr. Jaffrey trephined the skull over the middle of the Rolandic area. On dividing the dura mater it was seen that pulsation was absent and a considerable quantity of cerebro-spinal fluid escaped. A grooved director was passed under the dura mater in all directions, and while the fluid was escaping the brain began to pulsate again. He did not explore the brain. A drainage tube was inserted and kept in for three days. The fits ceased, but the boy made little progress for a fortnight, after which he improved so rapidly that at the beginning of September he was on the point of leaving the hospital when he had another attack of convulsions and again became unconscious. He remained in this condition for three or four days and then recovered. Since then he has had no further attack, but the parents say his memory is bad, and until this week he did not voluntarily use his right arm, but always used his left.

Dr. CAULEY stated that the diagnosis was extremely indefinite, and that on admission the boy seemed

rather intensely stupid than really ill. The headache was not localised, and there were no definite signs of cerebral abscess, tumour, meningitis or heat stroke. When the fits developed he had suggested operation with a view to relieving pressure. The localisation of the fits more on the right side decided the site for operation, and he had suggested at the time that the case might possibly be due to a latent abscess. There appeared little doubt that the operation was of very great benefit, and probably of vital importance. He could not suggest what was the exact nature of the cerebral mischief, and the recurrence of the attack a month later, with subsequent immunity, made the case still more puzzling.

Dr. W. EWART thought that the causation of the symptoms by excessive intracranial pressure had been demonstrated by the operation itself and by the relief which followed. The fact that on their second occurrence the same symptoms, presumably due to the same cause, disappeared spontaneously, suggested the view that transient effusions might be thrown out within the meninges, and soon reabsorbed again, as this had been shown to occur in the pericardium, the pleura, and the peritoneum. Alarming, but not necessarily fatal symptoms might thus be set up in susceptible subjects; but some of the worst forms of effusion and that formerly known as "serous apoplexy" might not be recovered from without surgical relief.

Mr. E. W. ROUGHTON showed a boy, *æt.* 5, who ruptured a congenital hydro-nephrosis by a fall. He removed the kidney. The specimen showed congenital stenosis of the ureter at its origin from the dilated renal pelvis. He also showed a man with partial rupture of the brachial plexus. An exploratory operation had shown that the 7th and 8th cervical nerves had been torn out of the intervertebral foramina. He then brought before the Society a case of internal derangement of the knee-joint. A loose transverse (inter semilunar) ligament had been removed by operation with a successful result.

CASE OF FRIEDREICH'S DISEASE.

Dr. L. GUTHRIE showed a man, *æt.* 24, who complained of difficulty in walking for twelve years and now exhibited the following symptoms of Friedreich's disease:—Ataxic reeling gait, unsteadiness on standing, especially with closed eyes, absence of knee-jerks, laboured, slurred, and indistinct speech, nystagmus on external deviation of the eyes, clumsiness and over-action in use of the upper extremities, antero-posterior kyphosis of dorsal vertebrae with lumbar lordosis. His discs were normal, muscular development and power good, choreic movements and lightning pains absent, sensation unaffected, intelligence unimpaired. There was no family history of the disease, nor of any other nervous affection, and no parental consanguinity. His personal history was peculiar. In August, 1889, he fell from a bicycle, and a few days later from a swinging gate, but appeared to have sustained only trifling injuries. A month later he complained of frontal headache, and rapidly lost the use of arms, legs, and speech, and feeding was difficult on account of spasmodic closure of the jaws. There were also twitching of the eyelids, mouth and hands, and jerking movements of the whole body and head, but no loss of consciousness, and no sphincter trouble. Dr. W. T. Newton, under whose care he was, thought the symptoms strongly resembled those of chorea. In November, 1889, he was admitted into St. Bartholomew's Hospital under the care of Sir Dyce Duckworth, when the only symptoms noted were weakness of the legs, spastic gait, loss of knee-jerks, tenderness of the cervical and dorsal vertebrae, drawing monotonous voice, and a faint systolic mitral bruit. His condition has therefore not appreciably changed for twelve years. The apparent onset of the disease might have been an attack of genuine chorea, but Friedreich's disease was not uncommonly mistaken for chorea. It was, however, most unusual for the choreic movements in Friedreich's disease to subside, as in the present case.

Mr. JAFFREY showed a woman, *æt.* 58, with multiple tumours on the forearm. Several small swellings were noticed fourteen months ago, and caused so much pain that she could not do her work as a charwoman. There

was no history of syphilis, but a strong family history of phthisis. On the outer side of the upper part of the right forearm were several small, very hard, prominent subcutaneous tumours, variable in size, movable on the subjacent tissues and under the skin. The induration diminished under potassium iodide. One of the tumours had been removed for microscopical examination. The diagnosis, he thought, lay between gummata, fibromata and sarcomata. Bazin's disease had been suggested.

The cases were discussed by the President, Dr. Ewart, Mr. Boyd Joll, Dr. E. Guthrie, Dr. C. F. Jaffé, Mr. F. Jaffrey, and Dr. Cautley.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JAN. 3RD, 1902.

The President, Mr. ALFRED COOPER, in the Chair.

THE adjourned discussion on Mr T. E. Atkinson's paper on "The Small pox Epidemic" was opened by Dr. LEONARD DOBSON with a paper on

GLYCERINATED CALF LYMPH.

A discussion followed. Dr. EDDOWS drew attention to the importance of the care of the vaccinated arm, and Dr. CLIPPINGDALE commented on the especial necessity of this on the part of those practising among the poor, including public vaccinators.

Dr. REECE spoke on the Government requirements in public vaccination, with regard to the area of vaccination, the inspection and treatment of the arm after vaccination, and the inquiry into deaths following vaccination.

Dr. GARRY SIMPSON related his experience with regard to re-vaccination, and drew attention to the necessity of extreme care in the details of the act of vaccination itself, as well as in the after care of the arm.

Dr. BEVAN spoke on the importance of using an active and trustworthy vaccine lymph.

Dr. CHAMBERS pointed out that the degree of protection conferred by vaccination depended to a great extent upon the number of insertions, and that the term vaccination without a statement as to the number of insertions was vague and rendered statistics illusory.

Dr. BUTLER spoke on the difficulty in defining what constituted efficient re-vaccination.

At the close of the meeting a proposal was carried with reference to the advisability of the exercise of Government control over the manufacture and sale of vaccine lymph.

BRITISH LARYNGOLOGICAL, RHINOLOGICAL, AND OTOLOGICAL ASSOCIATION.

MEETING HELD FRIDAY, JAN. 10TH, 1902.

Dr. JOHN MACINTYRE, F.R.S.E., President, in the Chair.

CASES.

Dr. WYATT WINGRAVE exhibited a young man, *æt.* 18, who had been the subject of (unilateral) acute cellulitis of the larynx, believed to be due to a foreign body.

Mr. LENNOX BROWNE exhibited a female patient, *æt.* 14, the daughter of a medical practitioner, who had been the subject of adenoids, and in whom deafness, almost inarticulate speech, mental hebetude and chorea were prominent symptoms. After removal of the adenoids the patient, with the consent of Dr. Ferrier, had undergone breathing and movement exercises, which had led in two months to the doubling of her vital capacity, increase of her chest girth, cure of her chorea, and very marked improvement in her speech and intellect.

Dr. CULVER JAMES showed a female patient, *æt.* 18, suffering from aphonia, with loss of speech. The Fellows present confirmed the functional nature of the trouble.

Mr. MAYO COLLIER exhibited a female child, *æt.* 5, the subject of defective speech, associated with defective hearing, almost to the extent of deaf mutism, in whom great improvement in both directions had followed on the removal of a large mass of impacted cerumen which had probably accumulated and been undetected in consequence of a curious abnormality in the direction of the meatus. (Abstract of these remarks will be found on page 49.)

Mr. LENNOX BROWNE exhibited five patients, the subjects of lingual varix, one of whom was a medical practitioner, and the other four had been sent to him by hospital colleagues as examples in patients at present attending the out-patient department, a point emphasised by the President.

Mr. MAYO COLLIER referred to an extreme case of paroxysmal dyspnoea, the sole reason for which appeared to be lingual varix. Treatment by galvano-cautery had resulted in a remission which had now lasted three years.

Mr. ATWOOD THORNE exhibited a patient with deafness associated with nasal stenosis and hyperostosis at the isthmus of the external auditory meatus. Remarks were made on this case by the President, Mr. MAYO COLLIER, and Dr. WYATT WINGRAVE.

Mr. CHICHELE NOURSE showed a case for opinion which, having many signs of a malignant growth of the left vocal cord, had so improved under biniodide of mercury as to suggest its being a gumma.

The President suggested that the case should be watched and further reported on at the next meeting.

Mr. LENNOX BROWNE read the notes (1) of two cases of "Acute Ulcerative Tonsillitis," which had been followed by orchitis, with an acute pustular inflammation of the skin of the penis and scrotum; (2) of a case of "Posterior Tongue Tie, with hypertrophy of the lingual tonsil," occurring in a female Board school teacher, *æt.* 23. A drawing illustrated that the epiglottis stood up, showing all its glossal surface, as well as the lingual tonsil. Removal of the latter, and snipping of the central glosso-epiglottic fold resulted in immediate restoration of the parts to the normal. (Dr. ABERCROMBIE, who had seen the patient both before and after treatment, testified to the striking peculiarity of the appearances as witnessed before and after treatment); (3) notes of a case of "Tuberculosis," in which, bacilli being numerous present, the patient showed continuous gain of body weight during four years of observation.

Dr. WINGRAVE spoke of the histological characters of the bacilli in this case, remarking especially on their tendency to degeneration with development of fresh organisms, and from the presence of pus corpuscles believed the case to be one of localised pulmonary abscess of a tuberculous nature.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 13th, 1902.

GELATINE IN THE TREATMENT OF BLOOD DISEASES.

M. LOMBARD read a paper at the Académie de Médecine on the therapeutic employment of gelatine in the pathological phenomena provoked by the variations in the plasticity of blood.

According to the speaker, diabetes, albuminuria, and hæmophilia were due more or less to the same cause, which consisted of variations in cryoscopic properties of the blood. These variations provoked in time hepatic, renal, or capillary alterations, in the same way that divers solutions disorganise the filters which were not made in view of that special filtration. Even when a lesion was anatomically constituted M. Lombard believed its cure could be obtained by bringing to its normal condition the plasticity of the blood. To reach that end he was in the habit of giving half an ounce daily of gelatine by the mouth, in solution, and in the cases in which he tried it the results were very encouraging; in some cases even a cure was obtained.

FATAL EFFECTS OF COCAINE.

M. Legueu communicated to the Société de Chirurgie two cases which terminated fatally after injections of cocaine into the rhachis. Both patients died on the

operating table. The first, a man, æt. 54, presented a rupture of the triceps of the left leg. The patient was afflicted with considerable obesity, and besides was emphysematous, had a florid face, the heart-beats were feeble, and the arteries atheromatous. Under these unfavourable conditions the usual anæsthetics were laid aside as dangerous, and injections of cocaine into the rhachis decided upon. At the end of three or four minutes after the injection, and while the operation was being done, the patient complained of oppression; he was placed in a sitting position, but the face became black and he fell back dead.

The second patient was a man, æt. 61, who was brought to hospital for strangulated hernia. The condition of the man was very unfavourable; pinched nose, livid face, tongue dry, the pulse was 140, and the temperature below the normal. In spite of these signs and symptoms an injection of cocaine was given, but before the operation could be commenced the patient gave signs of syncope, and although inhalations of oxygen and injections of ether were tried the man succumbed rapidly.

The speaker did not draw any conclusion from these cases, but considered that the counter indications of cocaine were not yet sufficiently understood.

THE STATE OF THE PARIS HOSPITALS.

The *Journal des Débats* has been investigating the condition of the hospitals in Paris, and the conclusion seems to be that many of them ought to be pulled down without delay. With a few exceptions the hospitals in Paris have been constructed with little regard to medical requirements. The majority appear to have been either established in old convent buildings, venerable but unhealthy, or in new barrack-like buildings. The result is that the venerable buildings encourage rats and smaller objectionable things, and the new ones are draughty and very badly arranged.

The revelations of the *Débats* will be what is colloquially termed "an eye-opener" for those, and they are the majority, who loll in the belief that the only weak point in Paris hospital administration is the difficulty of replacing the exiled Sisters of Mercy.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 11th, 1902.

THE *Prager. Med. Woch.*, 40/01, has a report of a CASE OF CIRRHOSIS HEPATITIS WITH GRAVE ANÆMIA, by Dr. Hokes. The case is a second one reported by the same writer, and although acknowledging that in many respects both cases show similarity to the disease known as Banti's, yet they differ from it in important points. The case now reported, like the first, differs from Banti's in there being no ascites, no splenic tumour, and no atrophy of the liver. The writer looks upon both cases as hypertrophic cirrhosis of the liver, with grave anæmia; whilst in Banti's cases there was atrophy. Opposed to the assumption of an essential pernicious anæmia was the moderate loss of hæmoglobin in the red blood corpuscles.

The *Deut. Med. Woch.* has a paper on the TREATMENT OF RUPTURE OF THE LIVER, by Dr. Wilms. Nineteen cases of this accident were treated in the Leipzig University Klinik during the past five years, and the author attempts

to formulate some generalisation as to the ætiology, pathology, symptoms, prognosis and treatment. The accident was almost always caused by crushing between the buffers of railway carriages or by being run over by vehicles. As regarded pathology the most varying forms of injury were met with. In most cases the right lobe was affected, occasionally there were one or more longitudinal rents, and occasionally a corner of liver was torn off or larger portion of the liver crushed, or destroyed portions of liver were found within the organ. These intra-hepatic destructions had generally been designated as apoplexies of the liver. When the injury was inflicted by blows, such as kicking by a horse, the pole of a waggon, cycling, the injuries were much of one kind. Below the external rent was a part that was crushed. Separation of a large part of the capsule was often observed, but this had little effect on the amount of hæmorrhage.

The diagnosis might be easy or difficult. Generally speaking, injury to the abdomen was easy to determine, and the liver was usually indicated as the part where the injury was caused by crushing between buffers or falls on the right side. It is generally found that pressure over the right side of the abdomen is painful, the body is drawn up, the abdominal walls tense, the patient complains of intense pain in the hepatic and gastric regions; in both dependent parts, but more on the right than the left, there is extensive dulness, and in such cases rupture of the liver is probable and laparotomy is indicated. The first thing to do will be to ascertain whether there is simple contusion or internal hæmorrhage, or laceration of intestine or injury, with severe hæmorrhage, or commencing peritonitis. The following appearances are to be noted: The face is pale and anxious, the skin sometimes covered with a slight sweat, the pulse may be regular, or small, weak, rapid, and easily compressed. The pain is general or localised over the stomach and liver, it is rarely of a radiating character from the shoulder. Painfulness on pressure is an important local sign. Pressure on the abdomen shows that the abdominal muscles are tense, and the side affected is even more tense than the other. Then below is the dulness on percussion that changes slowly on change of position. There may be vomiting—of course, some of the symptoms may be absent or more than usually pronounced. The presence or absence of icterus was of no importance as regards the need for laparotomy. As indications for this are the general condition, the presence of dulness in the lower part of the abdomen, and the tense condition of the abdominal muscles. If the indications are not sufficiently pointed the patient must be carefully watched for a few hours.

Prognosis.—From the collection made by Fraenkel, out of thirty primary laparotomies seventeen were successful. The results in the Leipzig Klinik were not so good, but there the operation was performed in many cases that afforded no prospect of recovery. Of the nineteen cases of rupture of the liver, fifteen were operated on at once and three of them recovered.

Bleeding was arrested by suture and packing with gauze. Slight rents were treated by suture. By several cases it was shown that even large ruptures could be successfully treated by suture. Packing was made use of in cases of extensive rupture.

At the Medical Society Hr. Mullerheim showed a preparation of

PERIVAGINITIS DESSICANS

from a woman, *set.* 35, in whom the portio vaginalis, as well as the whole vagina, necrosed, and was cast off. The patient was ill a fortnight, suffering from severe pain in the lower part of the abdomen and discharge, and had been treated by formalin injections. When first seen she had the symptoms of general sepsis; she was icteric, feverish, and had a pulse of 130. On the vulva was a large gangrenous ulcer, the clitoris and labia minora were destroyed, and the skin deeply undermined. Whilst cleansing the genitals a soft mass came into view, along with slight hæmorrhage. This was at first taken to be a cast-off placenta, but on more careful examination its tubular shape, lined with its rugæ remaining showed it to be the whole vagina. On examining the patient it was found that two fingers could be readily passed from the vagina into the bladder; the anterior bladder wall bulged towards the vagina. The uterus and adnexa were normal.

With treatment, washings, &c., the ulcer healed and the purulent cystitis improved. To prevent closing up of the vagina oily tampons were packed into it, and, at every dressing, care was taken to separate any adhesion that might be forming. The perivaginal tissues shrank however, and finally the vagina contracted to such an extent, as to be only the length of the thumb and just capable of admitting it. Closure of the bladder opening was of course, troublesome under such circumstances, but this was achieved eventually.

The cause of the trouble was difficult to determine, but he was of opinion that pus from an external ulcer had in some way penetrated into the perivaginal tissue and caused the destruction of the whole vaginal mucous membrane. He had discovered fifteen similar cases described in literature.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Jan. 11th, 1902.

TREATMENT OF ANEURYSMS.

At the "Gesellschaft der Aerzte" Eiselberg showed a trunk-maker, *set.* 52, who presented a pulsating swelling over the space between the adductors of the left leg. Examination revealed a large aneurysm of the femoral artery about twice the size of the fist, the artery being one and a half its normal size above this point. The heart and other vessels were normal. The patient had frequently complained of cold vermiculation and a boring pain in the left leg.

At the end of November last the aneurysm was totally extirpated. On examining the section microscopically two longitudinal oval slits were observed in the vessel walls, while the microscope revealed an enormous increase of the fibrous tissue between the two layers of the intima.

In his description of this operation he said he had performed eleven extirpations for this lesion—five in the popliteal space, four in the femoral, one in the brachial, and one in the temporal arteries. In all these cases the lesion was due to direct damage to the artery. Nine at least could be so attributed, although two were assigned to forced marches of sixteen hours at a stretch.

In all the cases the aneurysms appeared shortly after the lesion, such as stab from a knife, cut from a scythe, &c. In one of the cases, however, the aneurysm remained stationary for sixteen years, till one day it commenced rapidly to increase in size, demanding immediate operation. In all the cases save one the operation has proved a perfect success, the exception being one where resection of the vein was necessary on the dorsum of the foot, and this determined gangrene followed by erysipelas and death. The permanency of the recovery cannot be so dogmatically affirmed, as many of the patients returned in the course of two years complaining of "sleeping" of the leg, or formication and boring pain in it. In seven of them recurrence did not take place until after two years, and only two of the cases have remained perfectly well.

In one case the gangrene set in six weeks after operation, but this was very soon recovered from. In the case presented to the society the patient was attacked with a bluish black condition of the toes and foot. This may finally end in gangrene also.

IODINE REACTION FOR BACTERIAL DIAGNOSIS.

Grassberger and Passini pointed out to the society that on the sporulation of the butyric acid bacillus a granular condition is observed in the body of the microbe which takes up iodine greedily, producing the starchy reaction. This formation of starch points to a degenerative process, as frequently these cells are barren of spores, although the bacilli are strewn with starch granules. If these granules be cultivated and inoculated the reaction will be found negative; another proof of degeneration. In a few of the cases, however, these starchy granules germinated, but the clumping of the starchy granules pointed to the metamorphosis of death. These microbes, when carefully cultivated under anaërobic conditions in sugar-free agar, assume in ten hours an active non-granular appearance with flagellæ. Sporulation under these circumstances appears without any preceding granulation when cultivated in sterile meat. Infants' stools contain large quantities of micro-organisms presenting the iodine reaction, among which are genuine butyric bacilli. There is one species of these micro-organisms which closely resembles the Friedlander and rhinoscleroma bacilli.

In their researches they found that a large number of the micro-organisms respond to this iodine reaction, such as *Milzbrand*, the *spirilla* and *coli* class and more particularly if an old culture be raised on a 5 per cent. maltose medium.

MYOMATOSIS OF UTERUS.

Reinprecht showed a pathological preparation of the uterus in a case of uterus myomatosis, which had been removed by supra-vaginal amputation. In the left ileo-cæcal region there was a dermoid cyst about the size of a walnut. Further examination of the adnexa failed to discover the presence of a left ovary, while there was marked atresia of the left Fallopian tube.

From the history it seems that the patient, in her sixteenth year, had great pain in the lower part of the abdomen, with constipation, vomiting, and meteorism, and amenorrhœa of nine months' duration. From this it is assumed that some torsion took place, with displacement and probable strangulation, cutting off the nutritive supply, which subsequently led to degeneration and absorption of the left ovary.

THE HÆMOLYTIC POWER OF GLANDS.

Klein gave the results of his experiments with a 10 per cent. emulsion of the liver, spleen, kidneys, pancreas, and testicular organs. None of these gave a constant result, although the pancreatic emulsion was constantly found to be "lytic" in action. Again, the pancreatic extract is the only one that had the "lytic" action counter-acting the fowl serum action on the blood corpuscle of the guinea pig.

The influence of these emulsions on agglutination was also variable; the mucous membrane of the bowel being the only inhibitor of the phenomenon. Experiments *in vitro* gave similarly diverse results to those met with in the stomach and with subcutaneous injections. A mouse can take *per os* 300,000 times the normal subcutaneous dose of diphtheria virus. One gramme of the pancreas of a dog neutralises 10,000 times the lethal dose of diphtheria toxin in the guinea pig.

SOFT CHANCRES ON THE FINGERS.

Ullmann showed a young man with ulcers at the roots of the finger nails due to auto-infection. Duccraix's bacilli were found in all the ulcers. Extra genital soft chancres are very rare in comparison with true syphilis. According to statistics, out of 9,000 soft chancres, only five extra genital are recorded and eleven perigenital.

The Operating Theatres.

DREADNOUGHT SEAMEN'S HOSPITAL,
GREENWICH.

KRASKE'S OPERATION AFTER PRELIMINARY COLOTOMY.—

MR. WILLIAM TURNER operated on a man, æt. about 52, who had been admitted for continuous diarrhoea, notwithstanding increasing swelling of the abdomen, with no solid motions. These symptoms had been increasing for about fifteen months, and he had become very much emaciated. On examination *per rectum* a swelling occupying the whole lumen of the gut, but especially the anterior wall was felt, an inch and a-half from the anal margin; in the centre of this there was some broken down soft tissue, which was obviously growth; the finger could not be passed through it, and the attempt caused much bleeding and pain. It was found impossible to pass a No. 6 catheter through the stricture. The whole growth was freely movable, and was bulging into the lowest part of the rectum, simulating a low intussusception. Passing the finger behind it, the upper limit could be just reached with the tip. The abdomen was markedly distended and tympanitic, and the day following admission inguinal colotomy was performed (the single silk stitch through the mesentery being employed); the colon was found to be very distended. Four days afterwards the gut was opened. This relieved all symptoms of obstruction; the patient was then enabled to take solid food, and his health picked up considerably. Ten days afterwards, the growth having got perceptibly higher during the interval, the patient was again anaesthetised and laid prone upon the operating table, with his legs drawn up; an incision was made from about an inch from the posterior margin of the anus to the centre of the sacrum for about four inches and then curved outwards and to the left along the crest of the ilium; this incision was carried deeply down to the bone, and then the muscles and the ligaments were separated from the coccyx and the left side of the sacrum; in this

way the cellular tissue posterior to the rectum was exposed and the anterior surface of the bowel readily separated from its attachments; the coccyx was next removed and also the lower part of the sacrum to just below the level of the third foramen in one piece by means of a saw, slightly more being taken on the left side than on the right; the ligamentous and muscular attachments on the right side being separated as before. In the cellular tissue the rectum was easily found by the fingers and the lower portion just above the anus quickly separated and divided across. The growth was discovered to extend up about five inches; it was very carefully separated from the bladder, this being facilitated by a metal sound passed into the bladder *per urethram*; but during this process part of the left vesicula seminalis and the lower two inches of the vas had to be removed as they were found to be implicated in the growth. As this was being done the peritoneal cavity was opened and the upper part of the rectum which is covered by peritoneum, was exposed and drawn down, but with a great deal of difficulty. The rectum with the mesentery was then cut across about half an inch above the upper limit of the growth, part of the peritoneal surface being thus removed. The vessels were caught by Spencer Wells' forceps and tied, but with some trouble, owing to the depth of the wound. The peritoneal surface was then sewn up by a continuous suture, and the wound stuffed with gauze no stitching being put into the skin margins. The operation only lasted fifty minutes. Mr. Turner said his reasons for doing an inguinal colotomy first were the almost absolute obstruction caused by the growth and the general weak condition of the patient thus produced. The method employed in the colotomy was, according to his experience, extremely quick and very efficient, and the great complication of prolapse was practically avoided thereby. He thought it was quite unnecessary, from the cases he had seen, to spend time in stitching the peritoneum to the skin and then the bowel to the skin, when such results could be produced by the simpler method of merely using the single blanket, stitch through the mesentery, as described in Rose and Carless's "Manual of Surgery." The patient's condition, he pointed out, prevented the operation for the removal of the growth being thought about till after ten days, but as there seemed a likelihood of complete removal of the disease the facts were put before the patient, and he elected to have the operation done. As regarded the first part of the operation, Mr. Turner said he did not make the incision into the anus as the bowel just above the anus was healthy, although the likelihood of being able to remove the growth and bring the remaining portion of the rectum down to join the anus was remote. The removal of part of the sacrum was not carried out, he said, on exactly the same lines as described by Kraske, but time was saved by taking the whole of the lower part of the bone instead of only the left side. As is so often unfortunately found, he remarked, the extent of the disease was greater than had been anticipated, both upwards and anteriorly, five and a-half inches of the rectum being a considerable amount to be forced to remove, when the lower inch is left intact, and the vas and the vesicula seminalis being also implicated led to a dissection

which endangered very greatly the wall of the bladder. The left ureter, he pointed out, was not seen, though he had great doubts as to its being untouched after removal of the growth. The main dangers after the operation, he thought, were three:—1. Shock leading gradually to collapse, usually accompanied by 2, a considerable amount of oozing from so large a surface, and (3) peritonitis, with or without prolapse of the bowel, the best chance of avoiding which is, he considered, to pack the wound carefully with gauze, especially in this case, as it was found quite impossible to bring the lower end of the upper and remaining part of the rectum out to the skin margin, and this led to a great danger of sepsis and septic peritonitis.

The patient unfortunately succumbed to asthenia on the fifth day. At the post-mortem it was found that the whole of the growth had been successfully removed; the ureter was untouched, but there was some prolapse of small intestine into the upper part of the operation cavity. There were no signs whatever of peritonitis.

WEDNESDAY, JANUARY 15, 1902.

THE CONSUMPTION SANATORIA QUESTION.

We are in imminent danger of going off on a wrong track in the matter of the provision of sanatoria for the open-air treatment of consumptives. Following the example set by the Brompton Hospital for Consumption and other similar institutions, the tendency is to devote the large sums now becoming available to the construction of more or less palatial edifices in which but a comparatively small number of patients can be received. It is impossible to over-estimate the importance of striking out a new line in the direction of discarding the plan of sinking money in buildings of this class and of substituting cheap erections on a scale commensurate with the demand, admitting of displacement from time to time as occasion may require. The question of expense is all important because, unless the funds are judiciously expended only the merest fraction of the

tuberculous sick can be treated on approved principles, and until it has become possible to admit to treatment all who may apply, the idea of stamping out, or even checking, the ravages of this disease must be abandoned as chimerical. There is no lack of sites suitable for the erection of sanatoria for the tuberculous poor, and we have it on very good authority that results equally good as, if not indeed surpassing, those obtained in brick and mortar hospitals, can be secured at a fraction of the cost of the latter. If we insist somewhat emphatically on this point it is because there are rumours that the munificent donation due to the generosity of Sir Ernest Cassel is to be expended in the building of a sanatorium to accommodate at most from eighty to a hundred patients. When we reflect that the treatment is essentially one of long duration, extending as it often does over months and even years, it will be seen that the good accomplished by such an institution must be restricted to very few. At the Mount Vernon Sanatorium at Hampstead the treatment is limited to three months, with the result that no cures are to be recorded, although in most instances a certain degree of improvement has followed. But what is the plight of the patients who have improved as the result of their three months' sojourn there? They return to their ill-ventilated homes and inadequate nourishment, they, or many of them, resume their occupations under more or less unhygienic conditions, and, we doubt not, within a short space of time they relapse into their former plight and the benefit of the brief period of treatment is forfeited. It is painfully obvious that there still remains to be devised a broad general scheme which shall deal with this gigantic problem on the only lines which can make for success. Should His Majesty give his sanction to the present costly and inefficient plan of providing for the few instead of for the many an example will be set which cannot fail to be productive of very great evil. It is to be hoped that His Majesty's advisers will take a broad view of the problem before they have committed themselves to any definite expenditure. What is wanted is a large number of light wooden houses distributed all over the kingdom on suitable sites, constructions which can be destroyed and re-erected elsewhere from time to time, without the costly administration which absorbs such a large proportion of money contributed by the charitable in our large general hospitals. If His Majesty would set the example it would be quickly followed by local authorities, the more readily because the cost would not be prohibitive.

CEREBRO-SPINAL MENINGITIS.

DURING the epidemic of cerebro-spinal meningitis in Stuttgart in 1893 and 1894 Jaeger conducted a series of bacteriological examinations on the pathological specimens of the cerebro-spinal fluid and the nervous tissue that were then so freely obtainable, of the disease. The researches were continued from March, 1896, to June, 1901. During that time thirty autopsies were made, of which twenty were

on males. The ages of the deceased varied from six months to forty-seven years, and included acute, sub-acute, and chronic forms of the disease. Some of the acute cases were fatal in two days, and others less severe in fifty days. Briefly stated, the researches of Jaeger have confirmed the observations of Weichselbaum, made in 1887, who in that year discovered in the ventricular serum of a case of the disease, a microbe which he described as the *diplococcus intracellularis meningitidis*. He found that some of the microbes were readily stained, and some not at all, and concluded that those which he could stain had undergone degeneration. From experiments on animals he looked on the microbes as pathogenic of the disease. White mice were very susceptible to the influence of the microbe; injections into the pleura and peritoneum were constantly followed by the death of the animal, and the microbes were found in the exudate and in the spleen in large numbers. Hypodermically injected the serum containing the microbe produced no effect. Weichselbaum pointed out the characteristic differences between the microbe and the diplococcus of pneumonia. He had, however, only seen a few endemic cases of the disease and had lost no opportunity for examining pathological specimens from patients during an epidemic. Jaeger describes the microbe as closely resembling the gonococcus of Neisser. A culture of twenty-four hours produces a diplococcus or a tetra-coccus which is readily stained by methylene blue. It is immobile, is not reproduced by spores, and requires a temperature of 77° F. to 82° F. The colonies are very abundant on gelatine, and on agar and bloods serum and in hydrocele fluid. Its pathogenic action is feeble, but variable according to the species; white mice and guinea pigs are much more susceptible to its influence than rabbits. When given in a sufficient dose the effects are produced in twenty-four hours, and on examination the peritoneum is found to contain a large quantity of a viscid fluid, in which are found intra- and extra-cellular cocci, mostly in a condition of degeneration. The spleen is sometimes found enlarged, when this occurs the microbes are present in the blood. Animals that have recovered from toxic doses of the cultures, having had convulsive movements, tremblings, and so forth, are found free of the microbe on post-mortem examination. Subdural injection, after trepanning, was found to produce in the guinea-pig softening of the spinal cord and the presence of microbes. In the rabbit the same experiment produced no result. Microbe cultures produced from the guinea-pig serum were not more toxic than the ordinary ones. The pathological lesions found after a lethal dose of the microbe culture were: a purulent exudation on different points of the superior surface and base of the brain and cerebellum. The amount of pus and the number of the points are in proportion to the severity of the case. In severe cases the ventricles are distended with pus and bloodshot. In chronic cases that survive the meningitis the tissues

are found thickened and hardened, and hydrocephalus follows in still more chronic cases. Weichselbaum's microbe closely resembles the gonococcus, though not identical with it, and it may be looked upon as the pathogenic agent of at least one form of cerebro-spinal meningitis, and is found in some forms that are due to different causes. It may be a very long time before this knowledge can be made therapeutically available; nevertheless, it is a step forward toward the elucidation of the pathogenic causes of this obscure and terrible disease.

INTESTINAL ASEPSIS.

READERS of the clinical lectures of Abernethy, if to day there be any, cannot fail to notice the importance he attached to the use of saline purgation. He found from observation the good effects of the purge, but he had no theory for the practice. Later, the physicians who succeeded him told that the purgative acted by simply unloading the bowels. The question of the beneficial action of the saline purgative has been the subject of study by Kohlbrugge, who made a series of very interesting experiments on dogs and other animals. From these he concludes that there is a process of auto-sterilisation constantly being carried on in the healthy intestine, the intestinal secretions being bactericidal and normally all the bacteria that come in contact with the intestinal walls undergo chemical destruction, being reduced to inert products, and, of course, devitalised. The advantages of a saline purgative consist in its power to increase the secretions, a theory which offers a rational explanation of the value of drachm doses of Epsom salts in dysentery. The bactericidal property of the intestinal secretion, he believes, is derived from the blood, a theory which is supported by the observed fact that when the circulation in a segment of bowel is interrupted the bacteria augment enormously, and disappear almost as quickly if the circulation be restored. Coli bacilli swallowed with food are destroyed in the stomach, and even fæces when eaten by rabbits are sterilised by the juices of the alimentary canal. The influence on health of putrefactive intestinal changes is almost wholly due to the bacilli of the large bowel, and the numbers there vary greatly. Kohlbrugge concludes that the ordinary microbes of fæces are inoffensive and their importance is exaggerated, and further adds that the intestinal antiseptic remedies in no way modify the secretion. For purgatives and milk diet are our only means of staying putrefactive changes. We are reminded that the intestinal wall is a membrane which secretes actively, and one impermeable to bacteria. To facilitate secretion subcutaneous injections may be used. How far physicians will accept his views on the utility of chemical antiseptics in controlling putrefactive changes in the stomach and small intestines we cannot say. But we believe they will not meet with general approval. There are very few prescribers who have not seen good effects follow on the

administration of chemical antiseptics. We do not refer to pyloric stenosis with a distended stomach, where the food is simply undergoing fermentative and putrefactive change very much as it would do outside the body. But as a rule we think Kohlbrugge's paper will be accepted by the medical profession as conveying a great truth and a much-needed lesson. It may be said that he has done little more than repeat a truism, for Beaumont had long ago shown the antiseptic properties of the alimentary secretions. Nevertheless he has done well to once again remind his professional brethren that they have a valuable ally in the auto-sterilisation property of the small intestine, one more effective than ordinary antiseptics and readily made active by the administration of that old-fashioned remedy, the *sal mirabile* of the once famous Doctor Glauber.

Notes on Current Topics.

London v. Irish Qualifications.

OUR attention has been drawn to the report of the election of a medical officer for Staines Workhouse in which a supporter of one of the candidates is credited with having made remarks which, if not exactly derogatory towards, were at least depreciative of, Irish qualifications. The gentleman in question stated that Dr. B— was the more suitable candidate than Dr. D—, because he held "higher degrees, he being an M.R.C.S. and an L.R.C.P. of London, whilst Dr. D—'s diplomas were Irish." Anyone who held a London degree, said the speaker, must be particularly efficient. The result of the election was that the candidate with London qualifications was elected by a majority of one vote. We sympathise strongly with Dr. D—, but we are afraid that the opinion that London degrees are superior to Irish ones is bound to commend itself to an English Poor-law guardian, and that it will be difficult or impossible to eradicate it. In the first place, London is nearer to Staines than is Dublin, and in the next place London is a larger city. Either of these reasons is sufficient argument, so far as local English electors are concerned, for considering that London medical degrees must be deemed higher. The fact that those who are in the best position to judge do not consider the degrees of the English Colleges to be higher, or, for the matter of that, lower, than the Irish Colleges is not likely to trouble the head of an English rustic. If an ordinary man of business was asked to express an opinion on the merits of the two degrees, he being unprejudiced and knowing all the facts, we fancy he would be inclined to the opinion that the Colleges who were—so to speak—under the displeasure of the General Medical Council for endeavours to shorten their course would be the bodies whose degrees were least valuable. But putting this aspect of the question aside, it is quite time that these foolish notions of superiority were abandoned. Where there is a *bona fide*

ground for imputing superiority, as in the case of the degree of a teaching University, let such superiority be deemed to exist, not on the grounds that there is any marked difference in the quantity or quality of the medical teaching, but on the ground that the recipient is more likely to be possessed of a wider culture than is the non-University student. But when the comparison lies between bodies such as the English and Irish Colleges, the foolishness of endeavouring to maintain that the qualifications granted by the one body are superior to those granted by the other is evident, more especially when the basis for the supposition is that usually adopted. If the case to which our attention has been drawn were a more definite one in which the opinion as to the superiority of the London degrees had been an axiom laid down by the guardians as a body, we should feel it advisable and useful to draw the attention of the Irish Graduates' Union to the matter. Where, however, the opinion has only been expressed by a single member of the board, acting on his own initiative, we doubt the possibility of any effective action.

Small-pox in London.

THE small-pox outbreak in the metropolis is still increasing by leaps and bounds. Last week no less than 289 fresh cases were notified. On January 5th there were 30, on the 6th 56, on the 7th 53, on the 8th 33, on the 9th 37, on the 10th 34, and on the 11th 46. At the end of the first week in August there were 13 patients under treatment for small-pox in the Metropolitan Asylums Board hospitals. At a corresponding period in September there were 137; in October, 175; in November, 284; in December, 491. The figures since that time show for the week ending December 14th, 481; December 21st, 543; December 28th, 665; January 4th, 755; January 11th, 856. During the present epidemic over 6,000 cases have been treated in the Board hospitals. The total number of deaths from small-pox, including last week's returns, amount to 256. The distribution of these fatalities has hitherto been extremely unequal, from causes which it is not easy to determine, at any rate in the present stage of the outbreak. Thus, in St. Pancras, where the disease originated, there have been 44 deaths, 35 in Holborn, 25 in Stepney, 16 in Westminster, and so on in diminishing numbers to Kensington, Chelsea, Bethnal Green, and Paddington, which are credited with one apiece. At a most timely juncture the Metropolitan Asylums Board have published a valuable report of their Statistical Committee relating to small-pox and its prevention by vaccination. It seems incredible that the most rabid anti-vaccinationist could withstand the force of the following official statement:—"The total mortality-rate per cent. from small-pox of vaccinated cases was 14.21; of doubtful cases 65.09, and of unvaccinated cases 50.52." Not less weighty is the remark that "no greater argument to prove the efficacy of vaccination can be adduced than the fact that out of upwards of 14,800 cases received at the hospitals, only four

well-authenticated cases were treated in which re-vaccination had been properly performed, and these were light attacks. The facts given in this report cannot be too widely known, and it is to be hoped that their educational value will be appreciated by the medical profession as well as by the general public.

Case of Poisoning in a Hospital.

A SAD occurrence took place at Cork Street Fever Hospital, Dublin, during the past week, which resulted in the death of a patient—a girl, *æt.* 14. In the course of making up a prescription a quantity of carbolic acid was inadvertently added, with the unfortunate result mentioned. It appears that Dr. Day, the resident medical officer, who is in charge of the hospital and pharmacy, had as his assistant a gentleman who was fully qualified. Unfortunately, that gentleman was laid up, suffering from diphtheria, and it was found very difficult to get a qualified medical man to take his place. In consequence, Dr. Day was compelled to obtain the assistance of a young gentleman who was within a month or two of his final examination. At the time the mistake occurred Dr. Day and his assistant were in the pharmacy preparing medicine for the patients, and there was also a nurse present, who was employed giving out lint and ointment. The assistant asked the nurse to make up a mixture for a child. Unfortunately, the nurse took a bottle of carbolic acid, and, apparently under the impression that she was using the stock bottle containing the medicine required, poured a quantity of it into the patient's bottle. The coroner stated that so far as he could see the case was a pure misadventure. The jury found that death was caused by accidental poisoning. They wished to express their deep sympathy with the parents of the child, and recommended them to the kind consideration of the hospital authorities. The coroner quite agreed with the verdict and recommendation of the jury. We sympathise most sincerely with all concerned. The unfortunate occurrence appears to have been altogether due to the difficulty of obtaining a medical man as substitute for the assistant medical officer. It seems, however, a little strange that in a large hospital such as Cork Street there should not be a duly qualified resident or visiting compounder apart from the medical officers. We are sure the latter have ample work without the added duty of compounding.

Changes in the Returns of the Registrar-General.

STATISTICAL accuracy is clearly one of the foundation stones upon which the science of preventive medicine is built. Anything tending in that direction will, therefore, from that point of view command the careful attention of the medical profession. With the commencement of the year it is interesting to note that various important changes have been announced with regard to the weekly return issued by the Registrar-General from Somerset House.

First of all, the number of towns dealt with has been increased from thirty-three to seventy-five, a readjustment which will bring within notice no less than 45 per cent. of the population of England and Wales. So far as London is concerned, the list of causes of death has been modified, but at the same time care has been taken to preserve the means of comparison with the former list wherever that has been possible. The value of that precaution will be at once appreciated by those who have occasion from time to time to refer to the returns. Several of the less important diseases have been omitted from the list, and their place filled with maladies of a more definite and serious nature. At the head of Table IV., in which these changes appear, a note is made to the effect that some of the names retained on the list are printed in italics to draw attention to the fact that their use is objectionable either on account of their purely symptomatic indication, or for some other reason. Again, some of the large groups of diseases have been subdivided. "Phthisis" or "tuberculous" disease, for instance, is particularised by the addition of a more precise term, such as "pulmonary." The substitution of "tuberculous peritonitis" is suggested in place of the vague and misleading name "tabes mesenterica." Another important sub-division is that of the malignant diseases into three distinct groups, namely, the carcinomatous, the sarcomatous, and the more generally malignant conditions. Pneumonia, again, is to be separated into lobar and lobular and both forms to be distinguished in turn from the epidemic form of the malady. Other general terms that come under the official rebuke are puerperal fever, gastro-enteritis, and convulsions. It is to be hoped that the useful lessons thus inculcated will not be lost upon the medical practitioners of the United Kingdom, upon whose intelligence and accuracy the value of the vital statistics dealt with by the Registrar-General must ultimately depend.

Election to the King's Professorship of Institutes of Medicine in Dublin University.

THE President and Fellows of the Royal College of Physicians of Ireland met on Friday last to elect a successor to Dr. J. M. Purser in the chair of Institutes of Medicine in the School of Physic in Dublin University. It will be remembered that Dr. Purser resigned last autumn to the regret of everyone, because he considered that it would be for the good of the school that a new professor should be elected at a time which would give him the opportunity of supervising and selecting the fitting out of the new laboratory which has been lately built. By a resolution of the College, of October 4th, 1901, a special committee, consisting of the President, Dr. James Little, Professor O'Sullivan, and the King's Professors in the School of Physic, and the Registrar of the College were appointed to consider all applications sent in by candidates for the Professorship

and to report thereon. The committee went most carefully into the applications which were received and as a result, unanimously recommended Dr. W. H. Thompson, M.D., R.U.I., F.R.C.S. Eng., Dunville Professor of Physiology, Queen's College, Belfast, as the most suitable candidate for the post, and their selection was ratified by the College. Dr. Thompson is already well known in the University of Dublin, where he formerly held the post of Demonstrator of Anatomy, and will, we are sure, be warmly welcomed back. He received his medical education at the Queen's College, Galway, obtaining whilst there the first medical scholarship and a senior scholarship in anatomy and physiology. Dr. Thompson's qualifications for the post which he has obtained are well known. His communications to medical literature are many, and show that he has devoted himself with energy and capacity to the work he has chosen. At the present time he has in the press a translation of Pawlow's lectures on "The Work of the Digestive Glands." Dr. Thompson will, we are confident, prove a worthy successor to Dr. J. M. Purser. It is a position which it is by no means easy to fill, and we confess that it is with a feeling of pride that we learn that the Fellows of the Royal College of Physicians have not had to go outside Ireland to find a man whom they consider worthy to fill it.

Royal Medical Benevolent College.

WE learn with pleasure that under the will of the late Mr. France, Consulting Ophthalmic Surgeon of Guy's Hospital, a sum of money has been placed at the disposal of the Council of Epsom College to provide for aged and necessitous members of the medical profession. The election is vested in the Council of the College for the time being, following the regulations the donor formulated in the case of the ten female scholarships at the Royal Asylum of St. Anne's Schools which he purchased and presented to the College. Mr. France was a warm supporter of the institution from its initiation, and for many years was a most regular attendant at the meetings of the Council. This second benefaction, leaving the election of the pensioners in the hands of the Council, emphasises the confidence felt by the testator, derived from his personal experience, in the care with which the recipients of these great boons are selected by the governing body. The Council, at their last sitting, determined to found pensions of £30 a year, to be called the "France Pensionerships." The first election to these pensions will take place at the meeting of the Council on April 2nd.

Proposed Memorial to the late Dr. Kenny.

A CIRCULAR has been issued from the Mansion House, Dublin, inviting subscriptions to a proposed memorial to the memory of the late Dr. J. E. Kenny, City Coroner for Dublin. The circular has been signed by men of widely different views both in politics and religion, and echoes most truly contemporary opinion regarding the late Dr. Kenny. With his politics many disagreed, but for his steadfast-

ness to them and his constancy to his political friends through good or evil report, there was but one opinion. The circular before us is not, however, concerned with Dr. Kenny as a politician; it is concerned with him as a man, as a member of the medical profession, and as one who inspired all those who came in contact with him with respect and regard for him. His genial friendliness in the social circle, his kindly sympathy with his professional brethren— young or old—with whom he came in contact in the discharge of the duties of coroner, and his devotion to his profession and to his patients, will ensure a generous and speedy reply to the request embodied in the circular now being circulated. The form which the memorial will take has not been as yet definitely decided upon, but it appears probable that it will be that of a monument over his grave at Glasnevin Cemetery. Dr. J. P. Quinn, of 15, Westland Row, Dublin, is acting as hon. sec., and will be glad to acknowledge receipt of subscriptions sent towards the proposed memorial.

Ice in the Treatment of Tetanus.

FROM Indiana comes the report of the successful treatment of tetanus by the external application of ice by Dr. Ropers. The treatment was continued for four days, and the spasms gradually lessened in severity and frequency, and finally ceased altogether. The treatment by ice of idiopathic tetanus is so old that some of our contemporaries have come to describe it as new; but the late Dr. Todd (*Medical Gazette*) describes its use. He states "that he has seen great benefit from applying ice along the whole length of the spine. . . . When the cold finally reaches the spinal cord, its influence is shown by a marked depression of the heart, which turns to a general depression of the vascular system; if this depression becomes great, the use of the ice must be suspended." Again, in 1863, Dr. Chapman published his series of papers on the subject. Dr. Russell Reynolds, however, wrote unfavourably of the remedy: it utterly failed in his hands; about the same time the late Dr. Bennet published a series of contraindications to its use, and the use of ice as an external application to the spine in nervous disease was gradually discontinued. Under what conditions the ice proves useful, and what are the conditions in which it produces no good results have yet to be ascertained. The fact, however, remains that Todd, one of our most careful observers, found it useful, and that from Indiana comes the report of the successful use of this powerful therapeutic agent.

Lumbar Anæsthesia.

FRESH statistics bearing on the induction of anæsthesia by the injection of cocaine, or more rarely eucaïne, into the spinal canal, continue to be published. They can by no means be regarded as uniformly favourable to the use of the drug in this manner. Indeed, the statistics of some users render it difficult to understand what has induced

them to continue the administration of an anæsthetic to which such very unpleasant, not to say dangerous, after-symptoms are attached. Trzebicki, of Cracow (a), has injected cocaine in 138 cases. He succeeded in inducing anæsthesia in 103 cases. Failure to induce it often depended on individual peculiarities which it is impossible to determine beforehand. In some cases, the symptoms of intoxication were very severe—vomiting, convulsions, loss of consciousness for several hours, paralysis, and vaso-motor disturbances. An important discussion, which took place at Bier, on the subject of cocaine injections (b) does not lead one to regard this form of anæsthesia with any more favour than do Trzebicki's statistics. In 20 per cent. of cases, nausea and vomiting occurred. In 40 per cent., the pulse increased considerably in frequency, accompanied by a rise of temperature which sometimes reached 104° F. A subsequent headache was very constantly complained of, which in some cases lasted for three or four days after the operation. Syncope occasionally occurred in patients who did not maintain the horizontal position for some time after the operation. In one case paraplegic symptoms set in eight days after the operation, followed by insomnia and delirium of a maniacal form. On the whole we fear that the future of lumbar anæsthesia is not a very promising one.

Accommodation in the Ear.

It is now several years since Rumbold pointed out the function of the intratympanic muscles in regulating the selection of sounds, in other words, their power of accommodation in the ear as the ciliary muscle accommodates the eye to light. Professor Hensen, of Kiel, has recently investigated the subject and states that he had previously found that a transitory contraction of the tensor tympani muscle in the dog could be excited by the utterance or emission of a sound. The membrana tympani, which owing to its own rigidity ordinarily remained in a condition neither of tension nor of flaccidity, is thereby brought into a state of tension, and in its movement passed into the optimum position of accommodation for the perception of any given tone. When a tuning-fork is sounded, while at the same time a metronome was made to click, after each click a wave-like increase of the tuning-fork note is distinctly perceptible, and the same result follows other short-sound impressions. This, however, must be a contrast effect, or it may be due to accommodation, or it may be due to both. Contrast can be excluded by the following experiments:—If during the sounding of the tuning-fork the nostrils are actively closed at regular intervals, or the finger or other soft object is bitten, the increase of the note occurs in the same way, and always with the rhythm of the voluntary movements. Professor Hensen, who reported his work at the recent fifth International Congress of Physiologists, can find no other explana-

tion for this latter phenomenon than a simultaneous contraction of the accommodation muscle. Further, when attention is paid to a sounded note it does not disappear immediately, but recurs one or more times after the sound has stopped. This he also regards as evidence of accommodation in the ear. The subject is one of considerable interest and requires further investigation, as it would account for several phenomena of the sense of hearing which are at present somewhat doubtful.

Public Bacteriologists.

THE Cambridge Town Council has taken the important step of appointing a public bacteriologist. They are to be congratulated upon their enlightened policy, but the position thus raised deserves something more than passing attention at the hands of all interested in practical sanitation. There can be no doubt whatever as to the great value of a service for expert bacteriological examination in the prevention of infectious diseases, more especially in the case of diphtheria and enteric fever. Cambridge happens to have a well-equipped laboratory at hand, and to be well provided with a supply of competent bacteriologists. At the same time it seems absurd to offer an able man of that stamp a salary of £100 per annum. In times of epidemic it would take several bacteriologists to cope with the work of any moderately sized town, and it need hardly be remarked that it would be absolutely impossible for the Medical Officer of Health to undertake laborious work of the kind in addition to his ordinary duties. The more reasonable plan would appear to be in the union of several large towns or districts to maintain a staff of trained bacteriologists in a suitable laboratory. The hybrid chemical analyst and bacteriologist presents a peculiar combination of duties that can rarely prove satisfactory. By the way, a well-known Society journal some year or two ago published a coloured cartoon of a distinguished public analyst who grasped firmly in the hollow of one hand a culture tube in a way calculated to make a trained bacteriologist shudder and turn pale, but for all that he was a good chemist.

Professional Executions.

A LEGISLATIVE proposal recently thrown out by the Bavarian Government is not without a peculiar if somewhat sinister attractiveness. It seriously asked the State to legalise the putting to death of persons who were declared by several medical men to be the victims of hopelessly fatal disease. The executioner-in-chief was to be, of all men, a member of the medical profession. It is hardly to be wondered at that the proposal met with short shrift at the hands of a modern legislative body. In former days so transcendental a scheme would have had more chance of survival than in severely practical and humanitarian times like those in which we live. Indeed, in Sparta the deliberate sacrifice of human life was an accepted principle under certain

(a) *Wien. Klin. Wochens.*, 1901, No. 22.
(b) *Ann. Soc. Belge Chir.*, Mars, 1901.

conditions. As everyone knows, the Hindoos and the Chinese make a virtue of self-immolation under some circumstances. Were the idea carried out it is somewhat interesting to speculate on the way in which the medical profession would perform the rôle of executioner, and what weapons they would employ for the purpose. Incidentally, it might afford an apt illustration to the anti-vivisectionists, who are fond of picturing medical men as revelling in all kinds of bloodthirsty cruelty. The general public, however, will probably continue to regard their medical attendants as on the whole humane and harmless fellow creatures.

Utero-Fixation and Pregnancy.

WHATEVER may be thought of the utility in prolapse of the uterus of the operation of fixing the fundus uteri to the abdominal wall, by means of artificially induced adhesions, the procedure is one which ought not to be too readily advised in women still capable of becoming pregnant. Two cases reported in a recent number of the *American Journal of Obstetrics* show that the abnormal anatomical relations of the uterus determined by utero-fixation are incompatible with an uneventful gestation. In one case labour was followed by rupture of the uterus and fatal peritonitis, and in the other Cæsarian section saved the infant, but at the expense of the mother's life. If, therefore, the prolapsed condition of the uterus entail such distress or inconvenience as to render utero-fixation necessary, it would seem imperative in women who have not reached the menopause to take steps to prevent subsequent pregnancy, preferably by ligature of the Fallopian tubes, which, after all, would add but little to the gravity of the operation.

The Payment of Medical Fees in President McKinley's Case.

A SOMEWHAT novel point has arisen in connection with the payment of the surgeons who attended the late President McKinley. The dastardly deed was directed against the President of the Republic, and not against Mr. McKinley as an individual. He thereby became the patient of the nation, and the expenses incidental to his treatment cannot fall on the President's family any more than the punishment of the murderer. It will, therefore, be the duty of Congress to vote an adequate sum to indemnify the surgeons for the tremendous responsibilities which were theirs during the anxious period that intervened between the infliction of the wound and the fatal termination. This is a novel point that has not been raised, at any rate in public, in connection with similar regrettable occurrences in other countries.

Public Exhibition of Hypnotism.

PUBLIC exhibitions of so-called therapeutical hypnosis have fallen into discredit, and for some years they have ceased to attract the attention of the morbidly-disposed section of the public. "Dr." G. M. André and "Professor" Charles Howard have

revived the subject at a demonstration recently given in the Drawing-room of St. James's Hall. They went through the usual performances, with which most of our readers are probably familiar, but as only selected subjects were operated upon it is obvious that there must have been free scope for fallacy. Without questioning the genuineness of the phenomena we cannot but ask what benefit is likely to accrue to anyone from witnessing feats which are painful—to the observer—when not absolutely repulsive.

Closure of a Women's Medical College.

THE Women's Medical School at Chicago is about to close its doors. It has been in existence some thirty-two years, and has been "run" at an annual loss of 5,000 dollars. The failure of this institution appears to be due to the preference manifested by the majority of female students for what are called the co-educational schools—that is to say, schools at which male and female students pursue their studies in common. We suspect that the same preference would be manifested in this country if only it could find expression, but so far the doors of the general hospitals have been jealously closed to female students, and there is no present prospect of a relaxation of the taboo.

It is reported, we know not on what authority, that Miss King, the lady who voluntarily submitted to inoculation with bovine tuberculosis at the hands of Dr. G. D. Barney, has since developed pulmonary phthisis, thus proving the inaccuracy of Prof. Koch's views on the non-transmissibility of this form of tuberculosis to the human subject. It is added that Miss King is suffering from a decidedly irritant type of the disease. We give this information for what it is worth, and if confirmed we trust steps will be promptly taken to affirm the illegality of the experiment, and to bring home the responsibility of so reprehensible a deed.

THE annual general meeting of the Harveian Society of London will be held at the Stafford Rooms, Titchborne Street, Edgware Road, W., on Thursday, January 16th, at 8 p.m. The President, Dr. D. B. Lees, will deliver an address and the officers for the year will be elected. The meeting will be followed by a *conversazione*, at which will be shown illustrations of colour photography, and a collection of British butterflies and moths by Mr. H. C. Phillips. The evening will be enlivened by music, singing and refreshments.

THE Secretary of State for War has declined to accede to the suggestion of the Royal Institute of Public Health to appoint to the Medical Advisory Board a representative of sanitary science other than an officer of the Royal Army Medical Corps, on the ground that the present representation of preventive medicine on the Board by a thoroughly capable expert is sufficient. We may take this pronouncement as an intimation to a certain gentleman

who shall be nameless, that his services are not required.

PERSONAL.

DR. S. H. PERRY has been appointed Medical Officer of Health to the Spalding Rural District Council, at an annual salary of £200.

DR. CHARLES A. WEST, of Bodmin, has been appointed Visitor to the County Prison *vice* the Earl of Mount-Edgumbe, resigned.

DR. C. KILICK MILLARD has been elected President of the Midland Branch of the Incorporated Society of Medical Officers of Health.

DR. C. T. VACHELL, Honorary Physician to the Cardiff Infirmary, has resigned that post, which he had held for fifteen years, and has been elected Consulting Physician.

MR. EDMUND OWEN, surgeon to St. Mary's Hospital, has been appointed Consulting Surgeon and Surgeon-in-Chief to the French Hospital, in the place of the late Sir William MacCormac.

SIR FELIX SEMON and Dr. J. A. Ormerod have been selected by the medical staff of the National Hospital for the Paralysed and Epileptic to represent them on the reconstituted Board of Management.

DR. P. T. MANSON, son of Dr. Manson, the chief medical adviser to the Colonial Office, has left England to join Dr. Durham in a mission to investigate the outbreak of beri-beri in Christmas Island.

DR. MORTON, of Sheffield, met with a nasty accident last week, his horse having taken fright and pitched him out of his trap. His injuries were severe enough to justify his detention at the Royal Hospital.

TEMPORARY-MAJOR C. STONHAM, C.M.G., surgeon-captain Middlesex Imperial Yeomanry, has been granted, on relinquishing the appointment of officer in command and chief surgeon Imperial Yeomanry Field Hospital, the honorary rank of major in the army, with permission to wear the uniform of the corps.

COLONEL SIR T. J. GALLWEY, Principal Medical Officer of the Home District, has been selected for appointment as Principal Medical Officer in India, with the rank of Surgeon-General, succeeding Surgeon-General W. Taylor, who has been made Director-General of the Army Medical Service.

It was proposed to appoint Surgeon-General Price permanent successor to Surgeon-General Taylor as Principal Medical Officer in India, granting him at the same time an extension of service to enable him to retain the office for the full period; but, according to *The World*, these arrangements have fallen through, and an officer will be sent out from England to take up the duties, Surgeon-General Price reverting to his former position as Principal Medical Officer, Bombay.

We are glad to be able to contradict the reported death of Dr. W. G. Lawes, in New Guinea, on the authority of Mr. Sidney Spokes, dean of the National Dental

Hospital, London, who informs us that Dr. Lawes was recently in this country, and is now on his way back to the Antipodes. It may be added that the name of Dr. Lawes is intimately associated with New Guinea, he having been stationed there for the past forty years, and accomplished much in the civilisation of the natives, among whom he is immensely respected.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH ROYAL INFIRMARY.

THE annual meeting of the Court of Contributors was held on January 6th, when the annual report was submitted. From this it appears that 3,492 medical and 5,444 surgical patients were treated in the wards during the year, a decrease of 17 as compared with last year. The average daily number of patients was 701, the highest and the lowest being 759 and 591 respectively. The percentage mortality was 7.6 as against 8 in the preceding twelve months, or, excluding deaths within forty-eight hours of admission, 5.9. During the year 33,238 out-patients were treated, an increase of 783. The ordinary income was £33,552; the ordinary expenditure £50,044, or £71 ls. 9d. per occupied bed. Legacies and donations of £100 and upwards (the extraordinary income) amounted to £29,865. The capital expenditure has been unusually heavy, on account of the construction of two new pavilions, the remodelling of the kitchen and stores, and the reconstruction of the drainage system and heating apparatus, the total cost under this head being £41,100. The average number of nurses and probationers was 199, and 627 applications for admission as nurse had been received. The convalescent house income had failed to meet the expenditure by over £1,700; and the managers appeal for further subscriptions in aid of it, pointing out that during the year 1,258 patients, who must otherwise have remained occupants of beds in the hospital, had been inmates when they no longer needed special hospital treatment. Dr. Claud Muirhead, Sir Andrew Macdonald, Mr. Patrick Blair, Colonel McHardy, C.B., Miss Imlach, and Miss Louisa Stevenson were elected managers.

UNIVERSITY OF EDINBURGH.—ANNUAL REPORT.

During the past year the total number of matriculated students was 2,929, an increase of 176 from last year. Of this number the Faculty of Arts claims 906; Science, 167; Divinity, 29; Law, 402; Medicine, 1,403; and Music, 23. The number of women students was 272. Of the students of medicine 44 per cent. were Scotch, 23 per cent. English or Welsh, 17 per cent. Colonial, 8 per cent. Irish, 6 per cent. Indian, and 2 per cent. foreign. The medical degrees conferred were as follows: M.D., 61; M.B., C.M., 15; M.B., Ch.B., 180 (including 8 women). The total annual value of University fellowships, scholarships, bursaries, &c., now amounts to about £17,920 of which £10,480 go to the arts faculty, and £3,600 to that of medicine. Speaking of the Carnegie Trust, the report states that the benefit offered in accordance with the first purpose of the Trust deed—the payment of class fees—has been largely taken advantage of in Edinburgh, although the regulation requiring the University preliminary to be passed by intending *bénéficiaires* has so far told against any marked increase in the number of first year's students. An increase in the numbers attending certain honours and practical classes is probably due to the fund enabling students to attend a larger number of courses than they would otherwise have taken. In regard to the second main purpose of the bequest, a detailed statement of the requirements of the University is being prepared by the Senators and Court for submission to the trustees. The re-cataloguing of the library has proceeded during the past year, and a total of 178,000 volumes have now been dealt with. This covers almost the whole of the general library; the theological library has been com-

menced, and the medical and modern language will shortly be undertaken. Among changes in the office bearers of the University, the appointment of Professor A. R. Simpson as Dean of the Medical Faculty in room of Professor T. R. Fraser resigned, may be mentioned. The John Usher Institute of Public Health is approaching completion, and is expected to be ready for occupation by May 1st. It will afford much ampler accommodation for the Public Health Department of the University than it has previously possessed, and will provide a full laboratory training in the branches of study required by medical officers of health. The Hughes Bennett laboratory, gifted by Mrs. Cox in memory of her father, the late Professor Hughes Bennett, was formally opened in the course of the summer, and forms a much-needed addition to the Physiological Department.

Of new departures of special interest the admission of women to the Faculty of Divinity, the transference of examinations in Medical Jurisprudence and Public Health from the third to the final professional, and the institution of an "Appointments Committee" to assist students and graduates in obtaining educational posts may be mentioned.

SMALL POX IN GLASGOW.

During the latter weeks of 1901 a few cases of small-pox cropped up in Glasgow, but the number never reached two figures, and as no fresh cases were being notified it was hoped that the outbreak was at an end. Between December 27th and January 3rd, however, no fewer than fourteen cases occurred, twelve of which were removed from one model lodging-house in the affected area. Up to January 6th the total number of cases was twenty-nine, all of which are said to be of mild type. In view of the outbreak in a model lodging-house, Dr. Chalmers, the Medical Officer of Health, has sent a circular to all superintendents of such places, urging the necessity of a strict watch being kept, especially upon newcomers, and pointing out the advantages of having all the servants and other officials revaccinated. The necessity for greater supervision is clearly shown by the fact that in the house from which the largest number of cases was removed, one of the lodgers had been ill for nearly four weeks, and the character of the malady not having been recognised, most of the present cases were infected by him. It has been suggested in the Press that, considering the severity of the epidemic which Glasgow has just passed through, a system of regular medical inspection of all lodging-houses should be instituted until the disease is eradicated. At present it is practically limited to such places, and some such scheme would seem feasible enough; at all events, any additional expense incurred now will more than repay itself if the city is spared a second epidemic at all approaching the last.

GLASGOW WESTERN INFIRMARY.—AN ADVISORY COMMITTEE.

The following resolution has been passed by the managers:—"That the senior staff, consisting of the visiting physicians and visiting surgeons, the two physicians for the diseases of women, and the pathologist, be constituted an advisory committee for the current year, in order that the Board of Management may obtain their opinion on matters that may arise from time to time, and may be referred to them by the Board for consideration and report." Such an action cannot but conduce to that harmonious co-operation between the directorate and the staff which is essential to the well-being of a hospital. The Glasgow Western Infirmary thus comes into line with other modern hospitals in giving the staff a say in what concerns the working of the institution. In most of the Edinburgh hospitals this has likewise been conceded; for instance, in the Royal Infirmary, Edinburgh, though none of the staff have seats on the Board, they can make their voices heard through the representatives sent by the Royal Colleges, and there are, as well, medical managers appointed by the University and Court of Contributors. Similarly the Board of Management of the sick children's hospital, includes several medical men among its numbers,

one at least being a former member of the staff. The Deaconess's Hospital admits its staff to the Board of Management, and in the Leith Hospital, two members of the staff are annually elected to the directorate. The advantage of such an arrangement, giving laymen and medical men a chance of arriving at each other's standpoint, and thus obviating difficulties and misunderstandings which may arise, are so obvious that it is difficult to see why any lay board should hesitate to allow members of the staff to be represented on it.

Special Article.

SMALL-POX RETURNS.

THE Statistical Committee of the Metropolitan Asylums Board have prepared statistics of the epidemic of small-pox in London, which were laid before the Board on Saturday last. It must be borne in mind that the percentages are only provisional, in that the proportions are worked out only in respect of "completed cases," i.e., cases which have terminated in death or discharge. The cases were divided into three classes, namely—(1) "vaccinated"—i.e., cases having visible cicatrices; (2) "doubtful," which include (a) cases stated to have been vaccinated but bearing no visible evidence thereof, and (b) cases in which no statement was made, but in which the eruption prevented any reliable observation as to cicatrices; and (3) "unvaccinated"—i.e., cases admittedly unvaccinated, or bearing no marks of the operation, and as to which no statement was made. The total mortality rate per cent. of vaccinated cases was 14.21; of doubtful cases, 65.08; and of unvaccinated cases, 50.52. It was useful to consider the statistics as grouped under age periods. Under 10 there were only 12 vaccinated cases and no death; 6 doubtful cases, all of whom died; and 95 unvaccinated cases, of whom 52 died—a percentage of 54.74. Under 20 there were 161 vaccinated cases, of whom 3 died—a percentage of 1.87; 12 doubtful cases, of whom 7 died—a percentage of 58.33; and 161 unvaccinated cases, of whom 79 died—a percentage of 49.07. There appeared to be a distinct diminution in the protective power afforded by primary vaccination after the age of 20 years, the death-rate rising from 9.85 in vaccinated cases between 20 and 25 years of age to 28.95 in cases between 35 and 40. Among the patients admitted during the year there were 21 who were employed on disinfecting work (of whom 1 died), most of them being servants of borough councils. Not one of those persons had been revaccinated since infancy. There were also admitted 2 sanitary inspectors, 2 dustmen, 1 undertaker (who died), and 1 medical officer of an infirmary; and 3 other persons, 1 of whom assisted in removing a small-pox case from an infirmary, 1 scrubbed the ward from which a small-pox patient had been removed, and 1 made the beds in a lodging-house in which cases had occurred. All those persons ought to have been protected by revaccination. Against this they drew attention to the experience of the managers at their small-pox hospitals and in the ambulance service for many years past, in both of which services revaccination was always performed on engagement. Of 2,198 persons employed at the small-pox hospitals between 1884 and 1900 inclusive, in which period 17,900 small-pox cases were received into the hospitals, only 17 persons contracted small-pox, of whom 13 were not revaccinated until after they had joined the ship, and four were workmen who escaped medical observation. During the past year a very large number of the new staff had joined the ships and the Gore Farm Hospital, but not one case of small-pox had occurred. Not one of the staff of the hospital ships had ever died of small-pox, and not one had ever suffered from the disease for the past eight years. From the year 1881 to the end of 1901 there had been employed on the ambulance service of the Board 1,282 persons. Four of those persons contracted small-pox, of whom one escaped vaccination when appointed; he died; one was unsuccessfully revaccinated on joining the service, and the operation was not repeated; she died; the two others had been revaccinated and recovered.

The report was adopted and the Board directed that copies be forwarded to members of the London County Council, the metropolitan borough councils, the metropolitan boards of guardians, and other bodies, the secretary of the Anti-Vaccination League, and to any other applicants.

The number of patients under treatment in the Board's hospitals on Monday evening was 944.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

QUACK PUFFS IN HIGH-CLASS JOURNALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The enclosed four-page pamphlet on "The Hearing. Curing the Deaf, and how it is done," appears in the *Century Magazine* of this month. It is placed next to the ordinary reading matter, printed in similar type, and without any sign or hint to denote that it is really a paid-for puff. The pamphlet, for a production of the kind, is uncommonly well-written, so that the average reader might easily mistake it for a literary contribution to the magazine.

It is only in the last paragraph that the true nature of the article is revealed. Here we find the name and address of the "Drouet Institute," with the announcement that "free consultations are given by correspondence," and that a "charge is made for consultations at the Institute," &c., &c. Whatever the intention may be, there can be no doubt that the article, in such a form and place, is calculated to lead simple and confiding readers to look upon it as a *bona fide* production, and bearing the endorsement of the leading magazine in which it appears calculated to drive such readers effectually into the hands of the conductors of the establishment in question. If the advertisers were merely tradesmen engaged in puffing wares of equivocal quality, the publication of a puff of the kind in such a form for the sake of a little extra paltry gain would hardly be considered a very commendable business transaction on the part of so distinguished a firm of publishers as Macmillan and Co. Medical readers need no enlightenment as to the character of the so-called "Institute," and it is astonishing that an eminent house like Macmillans could lend themselves without inquiry to promotion of its questionable purposes.

I am, Sir, yours truly,

January 6th, 1902.

H. S.

DIET AND CONSTIPATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Allow me in the first place to apologise to your correspondent, Dr. John W. Martin, Sheffield, for my apparent discourtesy in not replying to his important questions in your issue of October 23rd, in which my paper on the above subject was discussed. I have been to India on professional work, and have only this week returned, and immediately on reading his letter in your columns I hasten to reply. I confess that my directions as to a dietary which will remove the cause of constipation based upon a uric acid diathesis are somewhat general, because I find it necessary to adopt my dietaries to the idiosyncrasies of each patient, but my answer to Dr. Martin's queries would be as follows:—

1. One pint of fresh milk may be looked upon as a fair average for a lady, and a pint and a half for a man.
2. The cereals that I prescribe are, very finely ground whole meal bread, Quaker or rolled oats, pearl barley, pearled wheat made into turnery, and for thin people I also use golden maize and hominy—all of these made into porridge, and eaten with honey and maple syrup and stewed figs in alternation.
3. With regard to salads it is happily possible nowadays in England to get salads all the year round. In summer there is a profusion of green salads, but in winter one is more restricted. However, even at the worst times one can generally get watercress, celery, sliced onions or garlic, and beet, while in most towns

you can also get lettuces and endive, and people who have cellars can always keep a supply of blanched dandelion and chicory leaves.

4. By "conservatively cooked" greens I mean greens in which the soluble salts have been preserved in the cooking and have not been thrown down the sink.

Some people, e.g., boil spinach in water, and when the spinach is cooked they strain off the water and serve up the boiled-out leaves. Those who know better either add no water or merely a few spoonfuls, so that when the spinach is cooked, there is nothing to throw away and all the salines remain in what is eaten.

If I can give any further helpful information, I shall be happy to do so, as my observations in India have added to my stock of knowledge on the subject, and to my conviction that a high percentage of cases of chronic constipation are caused by an incorrect dietary and can be permanently cured by prescribing one of the dietaries I advised in my paper on the subject.

I am, Sir, yours truly,

JOSIAH OLDFIELD.

5, Harley Street, W.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the autumn of 1900 you were good enough to allow me to call the attention of the younger metropolitan members of the profession to the advantages offered by the above society. The result was that last year we enrolled thirty-five new members. May I venture again to trespass on your kindness in order to point out that any qualified medical man residing within twenty miles of Charing Cross can be proposed as a member, the annual subscription being two guineas, payable for twenty-five years? But any annual subscriber may become a life member within ten years of his election by making up his subscription to twenty-five guineas if he shall have been under thirty years of age, to thirty guineas if he shall have been under forty years of age, and to thirty-five guineas if he shall have been over forty years of age at the time of his election as a member of the society. For the special benefit of young members I may point out that a member under thirty years of age at the time of his election can compound for a single payment of twenty guineas, under forty for twenty-five guineas, and over forty for thirty guineas, thereby becoming a life member, and his widow at once being eligible for a grant should her circumstances unfortunately justify it.

The Secretary is Mr. J. B. Blackett, 11, Chardos Street, Cavendish Square.

I am, Sir, yours truly,

CHRISTOPHER HEATH, President.

January, 1902.

Literature.

WILLIAMS ON THE ADMINISTRATION OF ANÆSTHETICS. (a)

THE object of the author of this excellent text-book on anaesthetics was to provide a practical guide, and he has kept his object well in view. He has not allowed his pen to run away with him, but has stuck to his text throughout.

He commences by reminding the anaesthetist that before beginning to administer the drug he should see that he has at hand all the necessary instruments for any accidental complication that may arise during the course of the operation.

Following this we have a paragraph on the time of day for operation, and a short article on the preparation of the patient.

Here we would suggest to the author the desirability

(a) "A Practical Guide to the Administration of Anaesthetics," By R. J. Probyn-Williams, M.D., Lecturer on Anaesthetics at the London Hospital Medical College; Assistant Anaesthetist at the Dental Hospital, London. (London: Longmans, Green and Co., 1901.)

of giving quinine for two or three days prior to the operation in full doses, five grains night and morning, or three times a day if it does not produce distressing cinchonism. We also think that the three hours interval of fasting before anaesthetisation is too long; we prefer that the patient gets a cup of strong beef-tea not more than two hours before operation.

Where from any cause it is considered advisable to use as little chloroform as possible a dose of chloretone given some hours before anaesthetisation is to be recommended.

The examination of the patient is an admirable piece of didactic writing which will commend itself to all practical anaesthetists.

Next in order follows the consideration of the position of the patient. The stages of anaesthesia are next dealt with and respiration and circulation naturally in this connection receive much of the author's attention, and nothing can be better than his opening sentence on page 18:—"The character of the breathing is one of the most important guides in maintaining the condition of anaesthesia."

We have said enough to make clear that the book is a trustworthy guide. It points out how dangers may be recognised, may be avoided, and how they may be combated.

There is scarcely a condition of danger that the author has not considered and his directions commend themselves as the outcome of a long, practical experience.

The letterpress is copiously illustrated so that the reader can the more readily understand the different anæsthetic apparatus in use, and the more easily follow the author's directions.

Laboratory Notes.

MERCK'S GLYCERINATED CALF-VACCINE LYMPH.

In view of the aspersions that have been cast in the public press on the efficacy of much of the calf-vaccine lymph in the market, it is important to make use of products emanating from firms of established repute. We have received some samples of Merck's Pure Glycerinated Calf-Vaccine Lymph, which is stated to be prepared under strict aseptic precautions by the method used in the Government laboratories. The samples in question are free from colour and but slightly turbid. The lymph is contained in capillary tubes, protected by a second glass envelope and a wooden case. Used to re-vaccinate some adults, it gave typical vesicles running a normal course without either œdema or undue erythema. Although it is claimed to retain its activity for a considerable time, it is obviously desirable, as far as possible, to use it and all other vaccine lymphs as promptly as possible.

Medical News.

British Medical Association.

THE twenty-fourth annual general meeting of the Dublin Branch of the British Medical Association will, by the kind permission of the President and Fellows of the Royal College of Physicians, be held on Thursday, January 30th, at 4.30 o'clock p.m., in the hall of the College. The officers and Council for the ensuing year will be elected by ballot, and any other necessary business transacted. Mr. C. B. Ball, F.R.C.S., President-elect, will deliver the annual address.

A New Hospital.

THE Hospitals Committee of the Metropolitan Asylums Board have decided to immediately proceed with the building of a hospital at Longridge, in the near neighbourhood of that already existing, at a cost of considerably over £100,000. It is expected that the hospital will be ready to receive patients in two months' time.

The Gresham Lectures.

A COURSE of lectures will be delivered in Gresham College, Basinghall Street, London, E.C., on Jan. 21st, 22nd, 23rd, and 24th, at six o'clock, by Dr. E. Symes Thompson, Gresham Professor of Medicine, on "Immunity from disease."

The lectures will be illustrated, and are free to the public.

New Universities.

EARL SPENCER presided over a special meeting of the Court of Victoria University at Owens College, Manchester. The gathering was called to consider what action should be taken in the event of a University Charter being obtained by University College, Liverpool. The report of the Special Committee was adopted, in which it was stated that both University College, Liverpool, and Owens College, Manchester had decided in favour of obtaining independent Charters. Yorkshire College deprecates the splitting up of the University, but expressed the opinion that should the dissolution take place the grant of a Charter to Leeds would be essential.

Deaths under Anaesthetics.

AN inquest was held last week on the body of a man age 66, who had died under the administration of the A.C.E. mixture, when about to undergo colotomy at University College Hospital. Dr. Dudley Buxton attributed death to cardiac failure consequent upon excessive vomiting, and a verdict to that effect was arrived at. A similar fatality, this time under pure chloroform, occurred on the 7th inst. at the Birmingham General Hospital, the victim being a man age 61. The administration of 150 minims of chloroform on a mask was promptly followed by collapse and death. The usual verdict was returned.

Bequests to Medical Charities.

By his will, the late Mr. James Alexander Molleson, of Edinburgh, has left the following bequests to local and other charities:—Trinity House Hospital Fund, £10,000; Longmore Hospital for Incurables, £2,000; Victoria Hospital for Consumptives and the Sick Children's Hospital, £1,000 each. The residue goes to the Royal Infirmary, Edinburgh. The total amount specially bequeathed is £18,500.

Orthopaedic Hospital of Ireland.

THE annual meeting of the Governors, subscribers and friends of the Incorporated Orthopaedic Hospital of Ireland, was held last week. The chair was occupied by Lord Justice Walker. The annual report, which was read by the secretary, contained the following:—The dispensary attached to the hospital has continued to do good work; 2,891 cases have been treated in this department, being the largest number in any year since its foundation. Many would have been admitted as indoor patients but for the want of accommodation. The Board, as well as the working staff, deplore the fact that many children have to be refused admission owing to this, and they again appeal to their friends and the charitable public to help them to obtain larger and more suitable accommodation now that the Corporation have taken the site in Tara Street from them, where it was proposed to erect a large Orthopaedic Hospital. The gymnasium has been found of great service, and an indispensable adjunct in the treatment of many cases of deformity constantly met with. The establishment of the county cots has enabled the Board to afford relief to many children from remote country districts. It is much to be desired that the funds of this excellent charity should be in such a position as to render it possible for them to erect an Orthopaedic Hospital which will be more in keeping with the needs of Dublin.

Society for Relief of Widows and Orphans of Medical Men.

At the quarterly Court of the Directors of this society, held on Wednesday last, the President (Mr. Christopher Heath) in the chair, two new members were elected, the deaths of four reported, and that of Mr. J. E. Upton, an honorary member, who for many years had kindly given his services as solicitor to the society. The election of a member was declared void. A fresh application for grants was made by a widow aged 74, and relief at the rate of £30 per annum given. It was resolved to distribute £1,282 among the 52 widows, 13 orphans, and the 4 recipients from the Copeland Fund now receiving half-yearly grants. The Christmas present, £569, had been given on December 18th. The expenses of the quarter were £77 7s. 6d.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be pared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

THE LATE R. B. ANDERSON FUND.

OWING to several requests and conditional promises of subscription, the Committee has resolved to keep this Fund open till the last day of February next instead of closing it January, 8th, as previously announced.

WALTER MONNINGTON,
Hon. Sec., 7, Fig Tree Court, London, E.C.

DR. S. M.—We hope to be enabled to carry your suggestion into effect within the near future, and will communicate with you in due course.

THE RELIEF OF PAIN IN PILES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The reporter of my note on a method of speedily relieving the pain of piles has evidently written c.c. for p.c. The words should be "10 p.c. of cocaine and 20 p.c. of menthol in oil of theobroma," and not 10 and 20 c.c., as printed at p. 30 of your issue for January 8th. May I ask you to be good enough to make the necessary correction?

Liverpool, January 9th, 1902.

Yours faithfully,

WILLIAM CARTER.

J. L.—Krohn's modification of Junker's regulating inhaler is the apparatus which we had in view. It is equally used in surgical as in obstetrical cases, and it enables chloroform to be given with a facility, a certainty, and a degree of safety previously unattainable.

HOSPITAL ABUSE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is stated in the daily papers that Mr. Max O'Rell, author and journalist, a gentleman whose literary ability must have secured for him ample means of subsistence, has just undergone an operation at the French Hospital in New York. Is this not another instance of hospital abuse? The hospital in question was presumably instituted for the benefit of the indigent poor, to which class no one will suspect Mr. O'Rell to belong.

I am, Sir, yours truly,

PRACTITIONER.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, JAN. 15th.

ROYAL MICROSCOPICAL SOCIETY (20, Hanover Square, W.).—8 p.m. The President will deliver his Annual Address.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George Street, S.W.).—7.45 p.m. Annual General Meeting.

THURSDAY, JAN. 16th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8 p.m. Annual General Meeting. Election of Officers. President's Address. Annual Conversations.

GUTHRIE SOCIETY (Board Room, Westminster Hospital).—8.30 p.m. Dr. Hall-Edwards: The X Rays in South Africa (illustrated by lantern slides).

FRIDAY, JAN. 17th.

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Meeting.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (Evelina Hospital).—8.30 p.m. Cases will be shown by Mr. A. H. Tubby, Mr. J. J. Clarke, Mr. Walter Edmunds, Dr. G. Carpenter, and Mr. F. C. Abbott. Papers.—Dr. L. Marshall (Nottingham): A Case of Thyroid Dislocation of the Hip in a Child.—Dr. L. A. Milligan: A Note on a Case of Chronic Granular Nephritis in a Child, aged seven years.

DUBLIN.

THURSDAY, JAN. 16th.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION (Front Hall, Trinity College).—8.15 p.m. Council Meeting Royal College of Surgeons.

FRIDAY, JAN. 17th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Surgery, College of Surgeons, 8.30 p.m.

SATURDAY, JAN. 18th.

MEDICO-PSYCHOLOGICAL SOCIETY (Royal College of Physicians).—Annual Meeting Dublin Branch.

MONDAY, JAN. 20th.

APOTHECARIES' HALL.—Final examinations commence.
ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—Final examinations commence.

Appointments.

BROWN, A. TENNISON, M.B., C.M., Aberd., Medical Officer of Health to the Hoxbury Urban District Council, Yorks.
CHIFFERFIELD, THOMAS JOHN BUSBY, FRASER, M.B., C.S. Eng., L.B.C.P., and L.M. Edin., Medical Officer for the Eighth District of the Lisaker (Cornwall) Union.
COLLINGS, HAROLD, M.B., M.R.C.S., L.B.C.P., Resident Surgical Officer to the General Infirmary, Leeds.
COLLINGWOOD, FREDERICK W., L.B.C.P. Lond., M.R.C.S., Anaesthetist to the Samaritan Free Hospital, London.
CRIPPE, HARRISON, F.R.C.S. Eng., Surgeon to St. Bartholomew's Hospital, London.
DENTON, STANLEY E., C.M.G., M.A., M.D., B.C. Cantab., Assistant Demonstrator of Anatomy in the University of Cambridge.
DICKMAN, HENRY GAO., M.B. Edin., Medical Officer of the Urban District Council of Diss, Norfolk, and Public Vaccinator No. 3 District (Diss) of the Norfolk Union, Norfolk.
MACKENZIE, W. H., M.D. Edin., Medical Attendant at the New Hospital for Infectious Diseases for the Kirkcaldy and district burghs, Fife.
MCCANN, FREDERICK, M.D. Ed., F.R.C.S. Eng., M.R.C.P. Lond., Physician to In-Patients at the Samaritan Free Hospital for Women, London.

Vacancies.

Bootle, Borough of.—Hospital for Infectious Diseases.—Resident Medical Officer. Salary £120 per annum, with board, washing, and apartments at the Hospital. Applications to be addressed to J. Henry Farmer, Town Clerk's Office, Bootle.
Bradford Royal Infirmary.—Dispensary Surgeon. Appointment for twelve months, renewable. Salary £100 per annum, with board and residence. Applications to William Maw, Secretary, Royal Infirmary, Bradford.
Doncaster, Borough of.—Medical Officer of Health. Salary £300 per annum. Application to Thos. B. Sugden, Town Clerk, Doncaster; R. A. H. Tovey, Clerk to the Halby-with-Berthorpe Urban District Council; H. M. Marshall, Clerk to the Wharfedale Urban District Council.
Durham County Asylum.—Junior Assistant Medical Officer. Salary commencing £140, with board, laundry, and attendance. Applications to the Medical Superintendent, County Asylum, Winterton, Ferryhill.
Joint Counties Lunatic Asylum for the Counties of Brecon and Radnor.—Medical Superintendent for the new Asylum at Talgarth. Salary £450 per annum, with partially-furnished house, coal, light, washing, and garden produce. Applications to Henry F. W. Harries, Clerk to the Committee of Visitors, County Hall, Brecon.
London, Corporation of.—Public Health Department. Female Sanitary Inspector. Commencing salary £125. Applications must be made on or before February 1st, 1902, to Monckton, Guildhall.
London Hospital, Whitechapel, E.—Assistant Director of the Pathological Institute at this Hospital. Salary £300 per annum. Application to G. Q. Roberts, House Governor.
Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary begins at £130 per annum, with board (no liquors found) lodging, and washing. Apply, by letter, to the Medical Superintendent.
Royal City of Dublin Hospital.—Resident Medical Officer. Applications to Mr. G. Jameson Johnston, F.R.C.S., 13, Lower Fitzwilliam Street. (See advt.)
Royal College of Physicians of London and Royal College of Surgeons of England. Research Laboratories.—Assistant Bacteriologist in the Research Laboratories. Salary £200 per annum. Applications to Frederick G. Mallett, Secretary, Examination Hall, Victoria Embankment, London, W. C.
Scalebor Park, Burley-in-Wharfedale.—Medical Superintendent. Salary £500 per year, with furnished house, board and attendance. Application to Messrs. Dixon and Morns, Asylums Department, County Hall, Wakefield.
The Royal Infirmary of Edinburgh.—Pathologist. Salary £400 per annum. Application to William S. Caw, Treasurer and Clerk.
The Royal University of Ireland.—Examiners in Surgery, Midwifery, Pathology, Ophthalmology. Applications to be sent to the Secretaries. (See advt.)
Whitecha. el.—Eastern Dispensary, Leman Street.—Resident Medical Officer. Salary £140 per annum, with furnished residence, coals, and attendance. Application immediately to George W. Illey, 60, Great Prescott Street E. (See advt.)

Births.

CARRUTHERS.—On Jan. 6th, at Halton, Cheshire, the wife of W. Hodgson Carruthers, M.D., of a daughter.

Marriages.

McSORLEY-LAWES.—On Dec. 26th 1901, at Enderby, British Columbia, Hugh S. McSorley, M.D., C.M., elder son of the late Rev. Hugh McSorley, Vicar of St. Paul's, Tottenham, to Mildred, daughter of Richard Lawes, of Enderby, formerly of Chester.

VAN SOMEREN-FLETCHER.—On Jan. 2nd, at the Parish Church, Northwood, Middlesex, Ernest Herbert Van Someren, M.R.C.S., L.B.C.P. Lond., of Venice, Italy, to Grace Ivy Ethel, daughter of Mr. and Mrs. Horace Fletcher, of Venice.

Deaths.

REID.—Godfrey Forrest Reid, M.D. Dub., Civil Surgeon, 8th Division, of The Bungalow, Bethlehem, O.R.C., shot on duty at Tweefontein Camp, Christmas morning, died Dec. 27, 1901.

Original Communications.

AN ANALYSIS OF SOME RECENT GYNÆCOLOGICAL METHODS. (a)

By H. MACNAUGHTON-JONES, M.D., M.Ch.,
M.A.O.

IDEAL ASEPSIS.

DISCUSSING in the first place whether an ideal asepsis were possible, Dr. Macnaughton-Jones maintained that, practically speaking, it was. This presupposed a perfectly constructed theatre with every aseptic appliance, and the most scrupulous attention to details in the persons and surroundings of the operator, assistants, and nurses. Summarising these essentials, he defined them to be a theatre capable of being well ventilated, at a temperature of 100°, with a supply of filtered air, well lighted, with tiled walls, and a concreted and drained floor, perfectly trapped, thus enabling all fluid to run from it without any possibility of infective reflux of gases; all washing sinks and baskets for dressings worked by foot pedal, and all the appliances capable of disinfection or sterilisation. It also involved the complete sterilisation of every material, whether in clothing worn by the patient or nurses, towels, bandages, compresses, dabs, sponges, and dressings. With regard to the preparation of the hands of the surgeon, assistants, and nurses, it took for granted perfect sterilisation of the arms, hands, and nails, not only before, but all through an operation, and the same might be said of the appliances and instruments used in conducting it. In such a theatre, and under these conditions, if the patient were properly prepared, an asepsis that might be called ideal could be secured. He continued:—

PREPARATION OF PATIENT.

What is involved in the preparation of a patient? Summarising the steps of such preparation we may include previous thorough ablution of the body, with careful shaving of the part, proper emptying and disinfection of the bowel, softening and disinfection of the skin of the abdomen, with thorough cleansing and disinfection of the vagina, and curettage of the uterine canal when necessary. Coming to the immediate preparations, if these be done in the theatre or an apartment adjoining, under the conditions mentioned, the body of the patient (nude, save for the aseptically covered upper and lower extremities), can be thoroughly disinfected by lavements with wood fibre sponge and izal soap, from the thorax to the thighs, first with sterilised water, next with perchloride solution, followed by perchloride of mercury and absolute alcohol. This should be done by an assistant, thoroughly sterilised, and with cotton or rubber gloves. Sterilised sack drawers are then drawn over

the flannel bandages which have been previously applied, the drawers reaching to the groin, and there loosely tied. A sterilised flannel jacket opening behind is then slipped over the trunk. Three pieces of soft muslin material, about two yards long by half a yard wide, are next taken, one having an oval aperture cut in the centre for the abdomen. The first is laid across the lower part of the abdomen and covers the drawers, the second is placed with the aperture over the operative area, the third meets the jacket, covering the chest above. All three are clamped together at the sides by sterilised sponge-holders or clamp forceps. These keep the coverings immovable during the operation. The skin inside the aperture, in the central portion, is now washed with ether, and the patient is ready for the incision. (a)

OPERATION AND TOILET, ABDOMINAL.

During an operation, asepsis means scrupulous care in the placing and replacing of instruments, the occasional dipping or boiling of these if necessary, periodical cleansing of the hands of the surgeons and assistants (each of the latter being confined to his own special duties), the rejection of instruments not re-sterilised, needles or others that may possibly have been infected in any step of the operation, the flushing and cleansing as far as possible of infected areas and cavities with weak formalin fluid, rapid and effective hæmostasis, with final cleansing from all remains of blood or coagula, and then proceeding to the abdominal toilet with freshly cleansed hands and thoroughly cleansed tissues and skin. Lastly, in the abdominal toilet itself careful adjustment of the layers, and the use for the cutaneous wound of sterilised non-absorbable material.

How should we close the abdominal wound? After careful readjustment of disturbed parts, such as the bowel and omentum, and having seen that the appendix is normal and in position, three deep sutures are carried through all the tissues with a Zweifel's needle from one side to the other, with the exception of the skin. These are long, and are allowed to drop at the sides, secured by forceps. Next the peritoneum is closed by fine continuous sutures of silk or cumol gut. Then the rectal fascia is separated with the handle of a scalpel, or the finger nail, at either side from the muscle. The fascia is then made to overlap by continuous or interrupted suture of sterilised gut, cumol or other. Lastly, the skin is closed by a continuous suture of bronze aluminium wire or the celloidinzwirn (of Braun), (a preparation of sterilised cotton saturated with celloidin), or with silkworm gut. [A demonstration of the two forms of the Zweifel suture was given.] The closed wound is now sponged with formalin solution, and dried. It is next covered with a few layers of sterilised iodoform gauze, over which is placed a layer of collaetin (zinc plaster, Säger's Klinik Prag), which reaches from the umbilicus to the

(a) Lecture delivered to the Cork Medical Society, January 13th, 1902.

(a) This method of preparation is a combination of those adopted in Professors Säger's and Bum's Klinika at Prague and Halle respectively.

groin, and is about ten inches wide. This, properly trimmed at the groin, makes an impermeable covering. Over this is placed a light layer of sterilised wool, and over all is drawn a tailed domette binder.

VAGINAL ASEPSIS.

In the case of the vagina, asepsis is secured first, by douching with lysol, then, thorough washing of the canal with izal soap and wood wool, next, by repeated sponging out of the canal and all its folds with dabs

Flushing Vaginal Retractor.

dipped in perchloride solution or formalin, and finally, plain douching out with sterilised water. During an operation a play of sterilised lysol water is kept up, or the flushing retractor of Leopold is employed. This latter is an admirable instrument, and is always under the control of one of the assistants, a tube connecting it with the douche can. In such operations as colpotomy, vaginal fixation, vaginal celiotomy and hysterectomy for carcinoma, disinfection and curettage of the uterine canal should be a preliminary step, and amputation of the cervix and closure of the wound by sutures, or amputation by means of Paquelin's knife will prevent subsequent infection. Of course, in a private "home" or house such ideal asepsis as we have indicated we cannot in many particulars hope for, but we can aim to arrive at it as nearly as possible, and only in respect to the suitable ventilation, heating and drainage of the room have we any insuperable difficulties in carrying it out.

SEPTIC COMPLICATIONS.

Should septic complications be present, such as pus abscesses, ruptured pus sacs, collections of septic pus, decomposing tissues, or possible contamination from the bowel, in irrigation with formalin solution and sterilised water, the iodoform (abdominal or vaginal) drain with effective mopping out of the various cavities in which septic material may collect, we have the best means of combatting septic consequences.

Already the speaker had advocated the resection of the edges of the abdominal wound after free cauterisation with Paquelin where a septic sac has burst and has had to be delivered, as in the case of the specimen exhibited, where a portion of the ectopic sac had become putrefactive. This course he had adopted in another case, in which a large septic accumulation had occurred in connection with appendicitis. The abdomen was thoroughly flushed out with formalin solution, and also mopped repeatedly with the same, until it was thoroughly cleansed and free from odour. Then the walls of the incision were resected before union, and an iodoform drain inserted. The patient made an excellent recovery.

DRAINAGE.

With regard to drainage, he held that reaction against it was setting in in perhaps too strong a direction. While, where not absolutely required,

it introduced a dangerous and unnecessary element into the method, on the other hand, he held that drainage was always indicated where the elements of future sepsis could not be removed, as, for example, where old pus sacs had been ruptured, where there was uncertainty of further bleeding, where communications with septic tissues or cavities had been made, and wherever drainage as an elementary step towards safe healing of parts was essential, as in various abdomino-vaginal and vaginal operations.

OPERATIONS FOR RETRO-DEVIATIONS.

In referring to operations for retro-deviations of the uterus, Dr. Macnaughton-Jones said that four procedures were all that it was necessary to discuss. The Alexander-Adams operation, which was that of selection in cases of freely mobile uterus, in which, for various reasons, an operation was indicated, consists of the isolation of the round ligament at its insertion, the opening up of the inguinal canal and processus vaginalis, the isolation of the round ligament at the internal abdominal ring, and the drawing of it forwards and securing it to the oblique aponeurosis, its ligature and section, with the doubling up of the cut end under the oblique fibres with careful aseptic closure of the canal. This was the favourite operation with many of the leading Continental operators, one that he had seen both Professors Zweifel and Menge perform recently.

Next, the operation of Olshausen, suitable specially for cases in which there were adnexal complications with the retro-deviation, and where adnexal operations of oophorectomy or resection with salpingostomy had to be performed or might be anticipated. This step involved celiotomy, free exposure of the round ligaments and adnexa in the Trendelenburg position, the folding of each round ligament on itself, and the suturing of it at either side to the peritoneum in front, this latter step following the interference with the adnexa. There was no doubt that this was a most complete and theoretically perfect operation. Neither of these procedures in any way involved the uterus. It had also been proved in practice to be a most favourable one for future parturition, and there was the great advantage that it enabled the operator to deal freely with the adnexal complications.

He now came to the two operations that included the uterus, namely, ventro-suspension by Howard Kelly's method, or ventro-fixation as performed by Terrier and others. The former was that which he had himself most frequently hitherto performed. It did not prevent removal or resection of the adnexa; it was done through a comparatively small wound of the abdominal wall, and with but little disturbance of parts. It secured the uterus with but little chance of any reversion to the mal-position. It had never in his hands interfered with pregnancy and delivery. In no instance had the uterine sutures given rise to any trouble. In it the fundus uteri is readily exposed, the adnexa explored, two sutures are passed posteriorly through the uterine fundus, and one anteriorly, all uniting the uterus to the peritoneum and sub-peritoneal fascia in front. These are not tied until the wound is thoroughly cleansed, and the peritoneum united. They are then tied, and the wound closed in the usual manner. Recovery is generally rapid, and mortality from the operation is practically nil. It does not certainly afford the same facility for dealing with adnexal adhesions, or tumours, as the method of Olshausen.

Finally, there was the ventro-fixation procedure, in which the uterus is fixed to the abdominal wall. In women past the childbearing period, and when the uterus is enlarged and heavy from

interstitial hyperplasia or possibly a small myoma, this was, he considered, the best operation. Personally, he never had a return of displacement after ventro-fixation, and though not now performing it during the childbearing period, he had known of several successful parturitions after it, and in only one case, where a transverse birth had occurred, had there been any evil consequences. In this method one thick gut suture was passed through the posterior wall an inch behind the summit, and carried through peritoneum, muscle, and fascia, at either side. Two thinner ones were passed, one at the summit, the other on the anterior wall, about two centimetres lower through the same structures. The peritoneum was then united with thin silk or gut, the fascia sutures were next passed, and the entire wound was then closed with the overlapping fascia, the uterine sutures being included. It was hardly necessary to insist on the perfect asepsis that all these operative procedures demanded, and more particularly he wished to draw attention to the need for complete hæmostasis, both arterial and venous, in the Alexander-Adams operation, which was typically an operation the success of which depended on the completeness of the antiseptic precautions taken. (a)

THE QUESTION OF PAN-HYSTERECTOMY OR MYO-HYSTERECTOMY.

In approaching the question of myomectomy or panhysterectomy for myoma, we touched a burning point of controversy among leading gynecologists. His own predilection was in favour of the supra-vaginal operation whenever it could be performed. It had these advantages: it was, as a rule, quicker, there were fewer chances of infection than when the vagina was opened, less danger to the ureters, it was of the two an easier operation, and it afforded a better pelvic floor. On the other hand, if there were any question of disease of the cervix, it left the woman still with a portion of the diseased organ, with some possibility, if not in some cases a strong probability, of further degenerative changes, such as suppurative endometritis, with erosion, a myoma, polypus, or possibly malignant changes. Again, there were cases complicated by broad ligament extensions, in which a cervical stump was difficult to make, and where it was not possible to satisfactorily remove the organ by the supra-vaginal method. Lastly, there was the large number of cases in which adnexal complications, suppurative or other, were present, and in these panhysterectomy was, as a rule, the best procedure. These might be taken as the most prominent indication for giving the preference to the latter step. Of course, it was the only one to be considered where malignant disease complicated the myoma. As to the question of removal of the ovaries with the uterus, he believed the answer experience taught was, that if there were any evidence of disease present or threatening in the ovary, it was better to remove it. On the other hand, if it were healthy, the leaving of one ovary tended to anticipate and prevent in younger women some of the post-operative physiological effects of the operation.

THE ABDOMINAL OR VAGINAL ROUTE IN HYSTERECTOMY FOR MYOMA.

The other question that had to be touched on was, the relative indications for the vaginal and abdominal route in operation for myoma by pan-hysterectomy. The only rational and safe answer appeared to be that it is advisable to perform vaginal hysterectomy when we are dealing with an interstitial submucous myoma or a subserous one in the pouch of

Douglas, of such a size that it may fairly be taken that it is suitable for the vaginal route. This will not be the case, even under the most favourable circumstances, should the tumour reach the size of the fetal skull at full term. Also there is the second condition, of a vagina and outlet of sufficient size and distensibility, and lastly, a sufficiently mobile uterus, and one free from adhesions.

Of the methods for performing hysterectomy, some were so well known and had been so critically discussed as to require no notice. The objects striven for, viz., reasonable rapidity of operation, rapid and secure hæmostasis, safety to the ureters and bladder, were obtained by different surgeons by different methods. One thing appeared to him certain—that apparent brilliancy of effect and rapidity in execution would never compensate for deliberation in carrying out detail, with a view to permanent and complete post-operative security.

The methods by ligature, with or without the aid of clamps, and Doyen's plan with his lever forcipressure clamp, combined with ligature, they were all familiar with. Everything considered, he believed

Zweifel's Broad Ligament Clamp.

that the method by ligature, assisted by the temporary use of clamp, not trusting to any crushing method, was by far the safest for the general operator to adopt, and best achieved the objects just enumerated. He would refer to two methods which he had seen performed this year, one in Halle, the other in Leipzig, by Professors Bumm and Zweifel respectively. The latter used a special forcipressure clamp after the method of Doyen, the degree of pressure being multiplied and regulated by the special mechanism of the instrument, which it was mathematically ascertained was multiplied three-fold at its blades. The clamp (shown) was applied to the broad ligaments, first at one side of the uterus and then at the other. After division of the ligament the cautery was used, and then double ligatures were applied of chromicised cumol gut. (a) The process is repeated at both sides. In myomectomy the uterus was shelled out from its capsule before the application of the clamp and ligatures. This considerably facilitated the removal of the myoma.

[Specimens illustrative of these disputed points were shown.]

Professor Zweifel used the same forcipressure clamp in vaginal hysterectomy, and had a small pressure forceps made on the same principle. It was worthy of notice how freely Professor Zweifel used the actual cautery in addition to the clamp to all suspicious bleeding points.

In the operation performed by Professor Bumm six pairs of Kocher's forceps were used at either side. Two of these light forceps were first applied, and the broad ligament divided above between them. Then two more, with further division of the ligament, and finally two others which involved the uterine artery in the section. There was practically no bleeding. (b) The same steps were taken at the opposite side, the uterus being now held only by its vaginal attachment. By the aid of an assistant pushing up with

(a) In some extreme cases of incontinence of urine from pressure of an inverted uterus, complicated with enlargement of the anterior wall, ventro-fixation in his hands was immediately followed by a complete cure.

(a) Prepared in the manner described by the speaker in THE MEDICAL PRESS AND CIRCULAR of December 11th, 1901.

(b) "Beiträge zur Geburtshilfe und Gynäkologie zur Technik der Myomotomie," Band I., Heft. I. 1898.

the finger from below, it was opened, and the final removal of the uterus completed, the vaginal vessels being temporarily secured by application of the same forceps. So far the operation was rapid and bloodless. The vessels at either side were now secured

Six Pair Kocher's Forceps applied to divided broad ligament.

with interlacing sutures from above down, the vagina closed and covered by peritoneum with the continuous suture. Cumul gut was employed for the operation, and bronze aluminium wire for skin. An iodoform tampon was placed in the vagina.

REMOVAL OF OVARIAN CYSTOMA BY VAGINA.

Removal of ovarian cystoma by the vagina has been recommended, and he had seen Professor Schauta, in Vienna, remove a large cystoma in this way. But the step involved a clear diagnosis of a unilocular cyst, and freedom from adhesions. To a simple parovarian cyst the method was applicable; the posterior cul-de-sac was opened, the sac felt and seized, and tapped with such a trocar as that he showed of Koeberle, and then the collapsed sac was readily drawn into the vagina. Still, on the whole, seeing the possibilities of errors of diagnosis, and the chances of unseen complications, while the mortality of such cases was almost nil, the advantage of the vaginal over the abdominal method was so questionable as not to make it in his opinion advisable.

CHOICE OF ABDOMINAL OR VAGINAL CELIOTOMY IN ADNEXAL DISEASE.

Touching on the important point as to the choice of abdominal or vaginal celiotomy in disease of the adnexal and adnexal tumours generally, speaking for himself, in the great majority of cases he gave the preference to the abdominal operation. These were his reasons. There was a better field of view, greater command over the affected organs, greater power of exact dealing with the ovaries and tubes in carrying out conservative measures, and in the event of inherent difficulties from adhesions, size of cysts, sacs, or solid growths, greater facility in dealing with them safely and of completely removing them. There were, however, cases in which undoubtedly colpotomy was the operation of selection. In simple parovarian cysts and small cystic tumours of the ovary, in cases of cystic disease of the adnexa complicating small interstitial myomata, or sub-peritoneal myoma in Douglas, in adnexal trouble

complicating retro-deviations of the uterus; in short, in those cases which were more or less of recent occurrence, the adnexal mass fairly movable and free from adhesions, with a mobile uterus, when by Martin's operation of anterior colpotomy, we can readily turn out the uterus into the vagina, and remove or resect the adnexa, the vaginal operation may be preferable. Should difficulty arise the advantage of morcellement by claw forceps and scissors, by Doyen's drill, or slicing of the uterus into segments (Landau), in those cases in which the reduction of the size of the uterus was imperative, was obvious. Some years since he found Schauta, in Vienna, performing all his vaginal hysterectomies by first bisecting the uterus so as to facilitate the manipulation of the adnexa and simplify the removal. Remembering, however, the frequency with which it is now shown that malignant and tuberculous degenerations affect the tubes and ovaries, and seeing the difficulties that may surround complete extirpation of all the diseased tissues by the vagina, it would seem that the cases were comparatively few in which the vaginal was preferable to the abdominal operation. [A number of specimens illustrative of the various points raised were again shown.]

This view of the relative advantages of the two operations was not, he knew, that held by some of the most distinguished authorities, such as A. Martin (the dearest vaginal operator he had ever watched) and Schauta, whom he had seen, on several occasions, perform the most difficult operations on diseased adnexa by the vagina. At the same time he had seen the attempt abandoned, as he had himself had to abandon it.

This brought him to the plan (the claim to the original idea being somewhat hotly disputed) of Kelly of proceeding to deal with the uterus by bisection from below upwards by seizing the cervix and drawing it up and then making an accurate coronal section. After bisection of the cervix the uterine arteries are secured and afterwards the round ligaments and tubo-ovarian vessels. The bisected uterus is then removed. Such removal of the uterus, it was claimed, afforded greater space for handling, greater facility for dealing with, and better access to, the diseased adnexa. (a)

CONSERVATIVE OPERATIONS ON THE ADNEXA.

There can be little doubt that in the conservative operations on the adnexa, both on ovaries and tubes, we have made one of the greatest advances in gynaecology. More and more we find it unnecessary to remove both ovaries, or indeed either, and with careful resection of cysts sufficient of ovary can be retained for future conception. He had had three cases of pregnancy at full term in which one ovary was removed, the other resected, and ventro-suspension of the uterus performed. At the same time it was advisable under all circumstances that the surgeon should have a free hand before operation as to the course he should deem it most advisable to pursue. In performing such conservative operations, where there are suppurative cysts of the ovary or purulent conditions of the tubes, it must be remembered that without complete removal of these we leave a nidus for future mischief and the possible necessity for a future operation. Also, a patient, notwithstanding all previous explanations, or her desire and determination not to have the ovaries removed if possible, was not as a rule considerate of any consequences due to the conservatism of the surgeon. There were also other considerations con-

(a) The Removal of Pelvic Inflammatory Masses by the Abdomen after Bisection of the Uterus. By Howard A. Kelly, M.D. "Johns Hopkins Bulletin," Vol. XII., No. 118, Jan., 1901; "St. Paul Med. Jr.," June, 1901; "Amer. Jr. Obs.," Vol. 42, No. 6, 1900.

nected with the condition of life of the patient and her physical necessities.

HYSTERECTOMY IN CARCINOMA.

As to hysterectomy in carcinoma uteri, there were four vital points for discussion did time permit. First, the necessity for the earliest vaginal pan-hysterectomy when the diagnosis of the disease was confirmed; secondly, the line of demarcation between operable and inoperable cases; thirdly, the best procedure to follow in abdominal pan-hysterectomy when the disease extended outside the uterus and involved the broad ligaments and pelvic glands; lastly, the best alternative measures in inoperable cases. He then referred to Wertheim's operation, which he had recently seen performed by Professor Gustav Klein in Munich—free exposure of the operative field in Trendelenburg's position, the separation of the ureter down to the cervix uteri from the fourth lumbar vertebra (recognising it by its peristalsis), isolation of the ureter from the uterine artery and ligation of the latter, removal of the uterus and the glands. As to alternatives, he thought that the choice lay between (a) removal of as much of the uterus as possible and the use of the cautery; (b) the treatment by the chloride of zinc method and amputation of the affected surface by the Paquelin knife; and (c) thorough cauterisation of the uterine tissues with either the steel or Paquelin cautery.

The lecture closed with a short retrospect as to the position of gynaecology now and at the time when, some twenty-two years ago, he (Dr. Macnaughton-Jones) performed the first successful ovariectomy in a Cork hospital. (a)

Paris Clinical Lecture.

LOCOMOTOR ATAXY AND SYPHILIS.

By DR. FOURNIER,

Professor at the Faculty of Medicine of Paris.

[FROM OUR PARIS CORRESPONDENT.]

MY subject to-day will be locomotor ataxy and its relationship to syphilis. I select this subject because I have in hand some fresh information which I am certain you will appreciate, and which will, I hope, complete the demonstration I have long attempted of the intimate relationship of ataxy and syphilis. I will give you in a few words the history of the problem. We may divide it into three periods: first, which I will call the period of incredulity, because, when in 1875 I expressed the opinion that locomotor ataxy was consequent upon syphilis. I was alone for a long time in my opinion. The second period was one of research. Clinicians studied and observed cases, but their opinions differed, for while some maintained that the affection was absolutely independent of syphilis, others considered that the specific malady might be the inciting cause in some cases, while others, again, among whom were Vulpian, Erb, &c., expressed their conviction that the majority of cases of ataxy were really due to syphilis. The third period is the present. To-day the proof is to hand, and everyone, in France and abroad, admits the close connection between the two maladies. You will find, however, in some text-books allusions to what is called *morbid coincidence*. The authors say:—"No doubt tabes dorsalis is often met with after syphilis, but of these two affections the first is not rare and the second is very common; there is consequently nothing very astonishing in their occa-

sional co-existence. The fact does not prove that one is the cause and the other the effect."

It is to destroy that argument that I imposed on myself the heavy task of collecting 1,000 cases during the last twenty-five years, and these I now bring forward to-day to convince the most incredulous. Special attention has been given to every one of these cases, so that they are in every respect perfectly trustworthy.

Here are the results I obtained: Out of 1,000 patients I found an unquestionable history of syphilis 925 times, which represents 93 per cent. Now, this enormous proportion is conclusive, and the few exceptions only serve to prove the rule. Yet even in the cases not directly traceable to syphilis, the reason may possibly be that the specific malady was so benign as to escape notice, or that it was hereditary or conceptional. This fact led Marion to the conclusion that if syphilis was found to have existed in the antecedents of 93 per cent. of patients suffering from tabes dorsalis, it existed in reality in the proportion of 100 per cent. Should I be justified in asserting that syphilis is the sole and only cause of tabes? No, and for two reasons: the first that I desire to limit my observations to my own strictly-controlled cases, and secondly, that the affection may be the result of various spinal affections. Syphilis, then, is not the only cause, but it is the principal cause, of ataxy. I will not further discuss this point, but will pass on to the study of hereditary ataxy.

It was believed for a long time that acquired syphilis could alone produce tabes, but it is proved to-day that hereditary syphilis is also a cause. I have notes of eight examples of this kind, and will give the history of one of them, which will serve for all the others. A girl, æt. 12, was brought to my friend Romak, presenting the following symptoms: Lightning pains, gastric disturbances, incontinence of urine, ptosis, diplopia, diminished vision from atrophy of the optic nerve, abolition of patellar reflex, &c., in short, all the classical symptoms of tabes. The affection had commenced three years previously; the father was syphilitic and infected the mother. The mother had eleven pregnancies, but seven terminated either by miscarriage or by the birth of a still-born child.

Let us now investigate another aspect of the question before us. Are there syphilitic infections which, more than others, expose the victims to tabes dorsalis? You know that syphilis is not the same in all persons, for, as you know, the symptoms vary considerably in intensity, but for the sake of nomenclature we will divide them into very grave, moderate, grave, and benign. Although it may be said that ataxy may follow any form of syphilis, yet in the great majority of the cases I mentioned to you 90 per cent. followed syphilis which at the onset was benign, and by benign syphilis I mean, the *small number* of the secondary symptoms which characterise them, the *slight nature* of these accidents and their *short duration*.

Is this predilection for the slight cases of syphilis special to ataxy and does it produce important consequences? No, for in the immense majority of cases, the benignity is the rule before the appearance of the tertiary symptoms, in a word, the graver tertiary period has the most frequently for antecedent a benign secondary period. If we take any tertiary symptoms whether it be cutaneous, cerebral, lingual, &c., we shall find that 99 per cent. were preceded by a benign secondary period. The fact is constant and should remain engraven on your memory.

A second point is this: Are all individuals affected with syphilis equally exposed to become ataxic? No. Locomotor ataxy threatens all syphilitics, it is true, but not all in the same degree. It has its chosen

(a) Illustrations and full descriptions of the methods and technique, &c., referred to in this lecture will appear in the *British Gynaecological Journal* (British Gynaecological Society's) for February, 1902.

victims, so to speak, and these are more particularly individuals who present what I term accidental causes, and of these I will mention three. The two first accidental predisposing causes of ataxy are nervous exhaustion and nervous heredity, on which Charcot insisted in particular, as you know. Nervous exhaustion is met with the most frequently as the result of irregular modes of living, excesses of all kind, more particularly venereal, social vicissitudes, worry, fatigue, reverses, late hours, debauchery, high living, nights passed at gambling, feverish excitement, &c.

The second accidental predisposing cause is nervous heredity. Tabes is frequently met in persons having among their ascendants subjects affected with nervous maladies such as hysteria, epilepsy, paralysis, hypochondria, mania, neurasthenia, eccentricity of character, &c.

The third accidental cause is the inadequate treatment of the syphilitic disease.

Such, gentlemen, is the ætiology of locomotor ataxy, which I will sum up as follows:—Principal, effective, and essential cause of tabes—syphilis. Accessory factors: Nervous exhaustion, nervous heredity, inadequate treatment of syphilis at the outset.

DIPHTHERIA. (a)

By FREDERICK S. PALMER, M.D., M.R.O.P.,
President of Durham University Medical Graduates' Association.
(Concluded from page 53).

Prognosis.—This is always doubtful. (b) "No case however mild, can be regarded as free from peril." Before the introduction of the antitoxin treatment, Oertel considered the mortality to be from 30 to 40 per cent. This has now been reduced to nearly half the number. The outlook is therefore materially influenced by the interval which has elapsed between the first manifestations and the adoption of the special treatment. The sooner it is commenced the greater are the chances of a successful issue. The prognosis of the neuritis is, in the milder forms, fairly good. A large number of them recover, and as Sir William Gowers says, (c) "the ultimate recovery is almost perfect," but many of the severe cases do not end so happily. The duration of the paralysis when limited to the palate and ocular muscles is normally from six to eight weeks. When the limbs are affected it may last for six months or longer. With reference to the incidence Sir William remarks:—"It is probably not far from the truth to say that on an average one-fourth of those who do not die from the primary disease subsequently suffer from paralysis."

Bacteriology.—The Klebs-Loeffler bacillus, or specific organism, is polymorphic and non-mobile, varying in length from 2 to 6 μ . It usually appears as a straight or slightly curved rod, with round or club-shaped ends. It does not form spores, and appears to multiply by fission only. Other bacilli are not infrequently seen bearing a strong family resemblance to the specific organism (pseudo-bacilli diphtheriæ) which exhibit the same staining and cultural behaviour. Their exact position has not yet been satisfactorily determined, or whether they may be regarded as attenuated varieties of the same organism. (d) The other bacteria observed chiefly in cases of mixed infection, are the streptococcus pyogenes, the micrococcus lanceolatus, the bacilli coli communis, and the staphylococcus aureus and albus.

Immunisation.—(e) The researches of Behring in

1882 led to the discovery that attenuated cultures of the bacillus injected into susceptible animals rendered them immune from diphtheritic infection, and that by the gradual repetition of the process, especially in large animals, a high degree of immunity could be thus obtained. The crowning result of his work was the revelation that serum taken from an animal so immunised has the power to neutralise to a large extent the virulence of the same poison when injected into man, and gave origin to the serum antitoxin treatment now in general use with such beneficial results to mankind. The duration of this protective power does not appear to last more than a few weeks—approximately a month—but during that period the protection conferred is said to be complete. According to Holt, quoted by Osler, "the serum is much less efficacious in the cases of mixed infection (septic diphtheria), and is valueless in the membranous inflammations which are due to streptococci." The serum injection is followed by an urticarial rash, and very frequently by the development of another exanthem, on or about the fourteenth day from the puncture, either erythematous, urticarial, or morbilliform in appearance, with joint pains, albuminuria, and occasionally an abscess at the seat of the injection.

Treatment: hygienic, local, general, and prophylactic.—All cases of suspected diphtheria should be immediately isolated, and when the diagnosis is established, removed if possible, to some hospital provided with a block, or wards for their reception. Everything not in actual use, curtains, carpets, furniture, ornaments, and the like must be taken away. To insure free ventilation a fire should be kept going in the room day and night; the air can be changed by opening the window at intervals, except it be in the height of summer, when it may remain open all the time. A nurse, or nurses, should be provided to take entire charge of the invalid, and communication with the rest of the household strictly cut off. Other children in the house, who have been in contact with the invalid, should not be allowed to go to school, but be kept under strict observation; and their throats gargled with some mild antiseptic vehicle. After recovery or other termination of the illness the apartment should be thoroughly and properly disinfected. The bedding and clothing are best purified at some professional disinfectors by a process of dry heat, or steam. The ceiling should be whitened, the painted work scrubbed with carbolic soap and water, and the paper removed. No books or toys used by the patient should escape destruction by fire. In the event of death early removal of the body is imperative, it should be enclosed in a disinfectant sheet, the coffin lined with the same material, and the interment conducted as privately as possible. Before leaving this subject to pass on to the local and general treatment, I should like to take advantage of this opportunity to say a few words of warning about the inadvisability of expressing a too confident opinion of the diphtheritic nature of an angina in the early stages of the disease, more particularly in the mild faucial forms. The most experienced practitioners have been mistaken. It is often impossible to say offhand what it is. An error in diagnosis involves the household in unnecessary alarm, and obloquy, frequently undeserved, is heaped unsparingly on the doctor, which a few hours' watching, supplemented by bacteriological information, might have avoided. More serious still is the premature removal of a patient to an isolation hospital who has no claim to this distinction. The mischievous, but I regret to add, determined attitude of the public to have an illness labelled at once with a definite name—to force our hands—before the means of doing so exist, should be, in my opinion, met with a stern resistance. A few hours' quarantine usually settles the difficulty,

and will prevent those bitter feelings of regret that I have heard expressed on more than one occasion. Once a definite diagnosis of diphtheria is pronounced, retreat becomes impossible, there is no middle course, no neutral ground to fall back upon. In these doubtful cases the compulsory notification of infectious diseases adopted by local authorities is not an unmixed blessing.

Local Treatment.—(a) The only external application likely to be of any service is a hot compress placed over the front of the throat. The remedies suggested for internal local application are antiseptics, solvents, and astringents. They are very numerous. I will only mention the favourites: Formalin 2 per cent. solution, mercuric perchloride, 1 in 1,000, carbolic acid, resorcin, creolin, salicylic acid, sulphur and sulphurous acid, chlorine water, potassium permanganate, hydrogen peroxide, Loeffler's solution of menthol, dissolved in toluol and perchloride of iron, boric acid and boro-glyceride, a solution of perchloride of iron in glycerine and water with a small quantity of carbolic acid, which in former years I always used. The favourite application by Dr. Voelcker at the Children's Hospital is salol in alcohol and glycerine; the results are considered to be satisfactory there. Among the solvent remedies are papain, lactic acid, pepsine, and trypsin. If local applications be adopted they should be efficiently carried out by experienced hands twice or three times a day. At frequent intervals the throat and nose may be gently sprayed or irrigated with a weak solution of boric acid. If, in very young children, the local application produces much distress or terror, I believe it is wiser not to pursue it; the resistance offered is trying to witness, and the efforts of the child are attended with great exhaustion.

General Treatment.—The experience of the last few years has placed beyond all controversy the beneficial results of the antitoxin treatment. A full dose should be at once administered. The amount injected does not appear to be important provided it be sufficient. At Great Ormond Street 3,000 units are given to quite young children; this dose is repeated in twenty-four hours, if the membrane exhibits any tendency to extension. In severe cases and in older persons it is better to commence with 6,000 units, and to repeat it the next day if no improvement takes place. The injections should be made into the subcutaneous tissue of the anterior abdominal wall, so that it may not interfere with the comfort of the dorsal decubitus. In the milder cases, one injection is usually sufficient. The patient must be kept in bed for at least three weeks, and not allowed to sit up for any purpose. The diet should be light and nutritious, given at short intervals, milk, beef-tea, chicken or veal broth, eggs beaten up, Valentine's meat juice, or some other preparation of meat in a liquid form, to which a little plasmon or somatose may be added. If any serious difficulty arises in deglutition or the nourishment is regurgitated through the nares, no time should be lost in resorting to rectal or nasal feeding. Bearing in mind that we are dealing with a disease of a distinctly asthenic character, marked by depression and leucocytosis, I am persuaded that the large majority of these cases require alcohol as soon as the symptoms are pronounced, the quantity ordered depending on the severity of the attack. In children, I always insist upon twenty or thirty drops of brandy in milk every four hours, in older persons either larger quantities, or port if it can be taken. Many of the sick with paralytic symptoms, take liquid nourishment better when it is thickened with arrowroot or Benger's food. If the dyspnoea becomes

urgent, it is safer to proceed at once to intubation or tracheotomy. No internal medicines are now given at the Children's Hospital until the throat has cleared. After the process is accomplished, a mixture of iron and quinine is prescribed. I confess that I still lean to the opinion that the tincture of the perchloride of iron, given in fairly large and frequently repeated doses, combined with potassium chlorate, has a beneficial influence on the course of the disease, but care is required in watching the effect of the potassium salt. Its value in local affections of the mouth cannot be denied. When there is evidence of cardiac dilatation, prostration, or tendency to syncope, digitalis or strophanthus should be given. At the same time strychnia by hypodermic injection must be administered. If delirium or typhoid symptoms supervene, ammonia, ether, and cinchona are the appropriate remedies, combined with free alcoholic stimulation. In post-diphtheritic paralysis the remedial agents resolve themselves into absolute rest in the recumbent position, frequent good, generous feeding, and the administration of strychnia, either alone or combined with atropine by the mouth, or by hypodermic injection. In cases where respiratory or cardiac failure is threatened, or when there is evidence of cyanosis, the inhalation of oxygen is demanded and galvanism may be applied to the præcordial region. Experience has not yet persuaded me that either massage or the use of the constant electrical current is of very great service in this form of toxic neuritis, beyond maintaining the nutrition of the muscles. Under no circumstances whatever should the patient be allowed to sit up in bed.

Intubation and Tracheotomy.—The clinical manifestations which proclaim the necessity for surgical measures are those of deficient aeration, noisy stridulous breathing, increased expiratory efforts, recession of the supra-clavicular, supra-sternal, and epigastric spaces, cyanosis, and drowsiness. Before us lies the choice of two alternatives, intubating the larynx through the mouth by a bloodless operation or opening the trachea below the seat of obstruction. In considering the claims of these two procedures. I venture on a territory which is strongly guarded by able advocates on either side. Before the days of antitoxin there is no reasonable doubt that tracheotomy held the field; but recently the pendulum has been swinging round in favour of intubation, at least, as a preliminary measure. It is true that in a small proportion of the cases, intubation has failed and relief has been afforded subsequently by opening the trachea; but even with this knowledge before me I am bound to admit that the latest statistics of intubation are very satisfactory. In practised hands and performed early, the method is steadily advancing in favour. The records at Ormond Street are exceedingly good; tracheotomy is now seldom performed at the Children's Hospital. Intubation gives quite as satisfactory results as tracheotomy, and the recoveries are much more rapid. In private or country practice the distance and absence of resident skilled help in replacing the tube if it should be coughed up are weighty arguments in favour of tracheotomy. The average time that an intubation tube has to be worn is from five to nine days; in tracheotomy it is frequently a question of weeks.

Prophylaxis.—It is obviously our business to protect as far as possible those persons who are, or have been, exposed to the contagion from falling victims to the ravages of this fell disease. With this object in view, and bearing in mind the protective power of the antitoxin serum, a dose of this fluid should be injected as a prophylactic. It need not be large; 1,000 units is sufficient for the pur-

pose. The trifling inconveniences occasioned by its use soon disappear; they cannot be compared with the probabilities of an escape.

AN EXPERIMENTAL PRODUCTION OF THE OSTEO-ARTHRITIC TYPE OF RHEUMATOID ARTHRITIS:

A CONTRIBUTION TO THE STUDY OF
RHEUMATOID ARTHRITIS (a).

By F. J. POYNTON, M.D., and ALEXANDER
PAINE, M.D.

In this paper the authors brought forward the results of an experimental investigation with a diplococcus isolated after death from the knee-joint of a man, *æt.* 67, who had suffered from arthritis. The cause of death had been carbolic acid taken by misadventure while engaged in his employment. Several joints were found much damaged by the arthritis, and the changes were such as are actually associated with the rheumatoid arthritis of later life. Thus, the fluid in the joint was almost clear and scanty in amount; there was a small body formed probably by the organisation of inflammatory exudation. The cartilages were eroded and the bones eburnated. The synovial membrane was much thickened. A diplococcus was demonstrated in the uninoculated and inoculated synovial membrane, and was isolated and cultivated upon blood agar.

From intravenous injection into two rabbits, arthritis resulted in both instances without valvulitis or visceral suppuration. One rabbit was killed upon the fifteenth day. No erosion of cartilage or alteration in the bones forming the joints was found. The other developed a monoarthritis of one knee with great wasting of the muscles of the thigh and leg. This animal was killed in the tenth week, and the specimen of the joint was shown to the Society. The exudation was scanty, and clear and sterile; the cartilages were in some places ulcerated, and had elsewhere lost their gloss. The articular surfaces were flattened; there was new formation of imperfect bone and cartilage, and lipping. The muscular atrophy was very definite. The joint capsule and periarticular tissues were but little thickened, but the crucial ligaments had lost their lustre and were swollen and opaque. A condition of osteoarthritis had therefore resulted from the intravenous inoculation of a diplococcus isolated from a case of rheumatoid arthritis.

This type of arthritis the authors had not observed hitherto as a result of inoculation with the diplococcus of rheumatic fever.

They pointed out that other observers had isolated micro-organisms from the exudations in rheumatoid arthritis. For example, Max Schüller, Bannatyne, Wohlmann and Blaxall; Chauffard and Raymond had isolated bacilli; Von Dungern and Schneider a minute diplococcus.

They emphasised the fact that the monoarthritis in their investigation was the result of an intravenous inoculation, and not of a direct injection into the joint, and summarised their conclusions as follows:

1. A diplococcus was present in the synovial membrane of the knee-joint of a man, *æt.* 67, several of whose joints showed the chronic destructive changes of one type of rheumatoid arthritis.

2. This diplococcus had been isolated and cultivated.

3. Intravenous inoculation into rabbits had upon two occasions produced arthritis without cardiac lesions.

4. The organism had been isolated from the joint exudations.

5. In one instance an osteoarthritis had resulted which was non-suppurative, and which differed in the character of the changes from that which they had hitherto observed in experiments with the diplococcus of rheumatic fever.

6. They, therefore, considered this diplococcus to be the cause of the arthritis, both in the case from which it was isolated and in the rabbit.

Cultures of the diplococcus were demonstrated, and section showing it *in situ* in uninoculated and inoculated fragments of the synovial membrane. The diplococcus of rheumatic fever was also demonstrated in the synovial membrane from a case of early rheumatic arthritis. Microscopic specimens of the arthritic changes were also shown, with pipette containing the fluid removed from the affected joints.

A CASE OF ASTHMA AND ITS TREATMENT.

By D. GOYDER, M.D.,

Hon. Consulting Medical Officer, Bradford Royal Infirmary.

E. W., a boy, *æt.* 14, who had been subject for many years to attacks of bronchitis, was seized on September 29th, 1901, with sudden and extreme difficulty of breathing. I found him propped up in bed with extended arms, staring eyes, anxious and somewhat livid face, and breathing with tremendous difficulty, all the muscles of respiration, head, neck and chest, exerted to the utmost in the heaving and gasping breaths he was taking. Beside these conditions he occasionally uttered sharp cries, not unlike the sudden scream present in meningitis. His appearance, indeed, was most painful to those around him, suggesting that, unless he was afforded speedy relief, he must sink from asphyxia and exhaustion. His temperature was only 101°, though his pulse was quick and irregular, about 130, his respirations being about twenty-four to the minute. The surface of the body was bedewed with a clammy moisture, and he had little or no cough and no expectoration. I at once prescribed for him a mixture with antimony, nitrite of soda and chloroform with an alkali, and ordered the application of heat to the chest and extremities, and the raising of the temperature of the room to 65° F. At 11 p.m. of the same day he was only very slightly relieved, therefore I ordered a tabloid of nitroglycerine every two hours, and the mixture to be given every half hour till morning. Next day, September 30th, the pulse and temperature were about the same, the dyspnoea and laboured breathing, dusky face were still very great, and the sharp cry, though less frequent was still present, but there was now occasional cough and some muco-purulent expectoration. In the absence of marked relief to the symptoms I determined to administer oxygen gas, and till I could obtain it, I added spirits of ammonia, and 5-grain doses of iodide of potassium to each dose of his mixture. The effect of the first dose of this was described by the father as magical, within a quarter of an hour of taking it the asthmatic spasm relaxed, his face speedily regained its natural colour, and muco-purulent expectoration was freely brought up. The relief was so complete that I diminished the frequency of the medicine to intervals of two hours, but determined to administer the oxygen notwithstanding, for though the relief of the asthmatic spasm was complete, I judged it necessary to support the respiration and improve the condition of the blood by the aid of the gas. I therefore directed it to be respired every two hours, and the air in the room to be improved by occasionally permitting the gas to escape into it at intervals during the day.

I need scarcely say that the case required anxious attention and care for some days after the relief of the spasm. The mixture with iodide of potassium, though

(a) Abstract of Paper read before the Pathological Society, January 7th, 1902.

given with diminished frequency, was continued for over a week, only being stopped when the breathing was perfectly free and tacit. After the third day, the cylinder of oxygen gas being exhausted, I thought it unnecessary to refill it, and the result justified this course: the boy had not the slightest recurrence of spasm, and may be said to have recovered his normal condition of health in ten days from his attack—that is, on October 8th. It is necessary to remark here that after the relief of the asthmatic spasm the temperature rose to 104°. The pulse, however, fell to 120, and became more regular. This rise of temperature is quite intelligible from the fact of the more perfect oxygenation of the blood after the relaxed spasm had permitted the air freely to enter the air cells. The temperature declined every day about a degree, and the pulse gradually fell until the eighth day, when both became normal.

Inquiry into the boy's condition previous to this attack elicited that he had what appears to have been only a slight cold, but seemed more than usually distressed. His previous bronchial attacks had generally come on after sudden barometrical depression and the appearance of a wave of air laden with moisture after a period of dry, warm weather. This fact was especially noticeable previous to this very severe attack.

The presence of his catarrh must have been associated with swelling and congestion of the minute bronchi, which would furnish just those conditions in which spasm is likely to be excited. His anxious and distressed state seemed to foreshadow the impending attack, and might be inferred by his possession of a highly strung nervous system, a condition of things generally associated with those who suffer the most severely from asthma.

The primary factors in cases of asthma which should strike one are the obstruction of the minute bronchial tubes, and the irritation of the nervous centres by the circulation of impure blood in them. What then were the conditions in the previous history of this case which brought about the tendency to spasm? It will naturally occur to you that the attacks of bronchitis in his earlier life, repeated every winter on the approach of cold and damp, must have resulted in alteration and thickening of the bronchial membrane, and the induction of the chronic form of bronchitis. This structural change generally involves the muscular and mucous coats of the bronchia, but in severe and continued cases the efforts at breathing exerted by the patient, are apt to result in dilatations of the cartilaginous part of the tubes, with consequent tubular emphysema and bronchiectasis. Examination in previous years in this boy's case proved that such changes were taking place in his instance—the shape of the chest elongated from back to front, and somewhat flattened at the sides, the resonance of the whole chest on percussion, the roughness of the bronchial sounds, the indistinctness of the respiratory murmur, and the prolonged expirations, were the accurate indications of these alterations. I had also observed in his previous bronchial attacks, more or less spasm of the minute tubes—his respiration had been laboured, but never to the terrible extent exhibited in his last attack. It may seem singular that with such impairment to the larger bronchial tubes, the smallest, up to the air cells, should yet retain their muscular coats to such an extent as to permit spasm and contraction of their calibre—under nervous influence and the consequent breathlessness—exhibited in asthma, but the singularity disappears when it is remembered that in the smallest tubes the mucous and muscular coats lie in direct contact without the intervention of any of the cartilages present in the larger bronchia.

In the treatment of this case it was somewhat of a disappointment that the first prescription, containing antimony, nitrite of soda and chloroform, and the subsequent administration of nitro-glycerine should have failed to relieve the asthmatic spasm; their failure to give more than very partial relief is explained by the fact that their influence has been proven to be exerted upon the circulatory rather than upon the mucous structures,

as in obstruction of the heart, congestion, and stasis in the vessels, with consequent angina. Nitrites are indeed recommended in text-books in cases of asthma, but their effects are only secondary, and not primary or specific. On the other hand, iodide of potassium is alleged to exert a direct antispasmodic effect upon the respiratory nervous centres, and thence through the pneumogastric on the lungs. Its influence, that is, the iodide of potassium, in glandular structures is well known, but it has besides been proven to exert a special expectorant effect in dry bronchial affections. This at once explains its immediate and beneficial action in this case of asthma. In cases of plastic bronchitis, in which organised casts of the tubes are expectorated, I have more than in one case proved its influence and efficiency in loosening the casts and favouring their expulsion from the tubes.

With regard to the use of oxygen gas in this case, I was induced to employ it because of the hope that it would assist in the oxygenation of the blood, but also because of an article by Dr. Given in the October, 1901, number of the "Phonographic Record of Clinical Teaching and Medical Science," published by the Phonographic Medical Society, "On the Use of Oxygen in Chronic Pulmonary Affections." Dr. Given alleges that in chronic and long standing cases of bronchitis and bronchiectasis, the systematic administration of oxygen gas breathed unmixed with air, deeply into the lungs for half an hour, three times a day, produces a most beneficial result after all other means fail. Cough, expectoration, and dyspnoea, steadily decrease under its use, and the bronchial membrane assumes a more healthy and natural condition. He gives a case illustrative of these effects on page 147 of the "Record." (a)

"To get this result the inhalations must be thoroughly and efficiently carried out. The oxygen unmixed with air should be drawn into the chest with fairly deep breaths from the vulcanite mouthpiece, which is usually supplied with the cylinder of gas; this mouthpiece is held in the teeth with the lips closed over it.

"In the case of one old patient of about 65 years, who had long suffered from chronic bronchitis with evidence of dilatation of the bronchia, the shrinking of one lung and repeated attacks of engorgement of both bases which now and then brought him to death's door, the use of the oxygen resulted in a most satisfactory state of affairs, one lung practically cleared up, and the other became very much better, and all moist sounds disappeared. Expectoration after having been profuse and offensive dried up, and the marked cyanosis of the face and extremities gave place to healthy colour. This patient was most enthusiastic, and took much trouble and care in giving himself the oxygen, he held the tap of the cylinder in one hand, and turned it on during inspiration and shut it off during expiration."

It is my intention to test the effect of this treatment on the young bronchitic who has been the subject of these remarks.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD AT THE ROYAL COLLEGE OF SURGEONS,
JAN. 10TH, 1902.

The President of the Section, DR. McWENNEY,
in the Chair.

DR. McWENNEY exhibited some microscopic slides showing the pathological changes that occur in the calf after the introduction of vaccine lymph, showing the presence of Guarnieri bodies in the vaccinated epithelium.

DR. EARL having been called to the chair,
DR. McWENNEY read a paper on the

(a) See page 147, October number of "Phonographic Record."

PRESENT STATE OF OUR KNOWLEDGE AS TO THE ETIOLOGY OF VACCINIA,

which was illustrated with lantern slides.

Prof. McWeeney in the course of his remarks referred to the fact, that having been entrusted by the Irish Local Government Board with the supervision of the production of calf-vaccine, he had naturally thought of undertaking a research with the object of ascertaining the cause of vaccinia. Before doing so, he had thought it well to carefully survey the ground that had already been covered by others and lay the present state of the question before the Academy. That vaccinia was merely small-pox, modified by passage through the calf, there can be no doubt, since the work of Von Thieme, Ceely, Voigt and Fischer. The microbic etiology of the two diseases must therefore be identical. Since the commencement of the bacteriological epoch repeated and unsuccessful endeavours had been made to establish a bacterial etiology for these maladies. As among the most recent of these attempts might be cited those of Klein, Copeman, Kent, Nakanishi, and of Czaplewski and Vanselow. Mann had demonstrated that in sections of vaccine tissue, appearances closely resembling micro-organisms, but really consisting of granular or rod-like precipitates of stain—mere artefacts—might be produced in the process of Gram's method. The bacillus of Nakanishi was at once recognisable by anyone familiar with the microbic flora of the calf's skin, as the Xerosis bacillus, which closely resembles that of diphtheria, but is harmless. The *Micrococcus quadrigenus* of the last named observers has been recently admitted by themselves to be devoid of all etiological relation to the vaccine process. The attempts to prove that variola and vaccinia are due to a parasitic protozoon were begun in 1886 by Van der Loeff, continued by L. Pfeiffer, of Weimar, and still further developed by Guarnieri, of Pisa, and by Pfeiffer's pupil, v. Wasielowsky. To Guarnieri belongs the credit of having selected as the field of observation the rabbit's cornea, a transparent, non-vascular structure, in which the histological events could be observed uncomplicated by the vascular and exudative phenomena of inflammation. Guarnieri saw in the epithelial cells of the inoculated cornea, rounded bodies varying in size from that of a minute coccus to about one-third of that of an epithelial nucleus. They lay in the protoplasm, often close to, and even indenting, the nucleus. Amœboid movements were observable on the warm stage, and Ernst Pfeiffer saw the bodies lying between the epithelial cells an hour after vaccination, and within them a few hours later on. Several observers, such as Ferroni and Massari, Salmon, and others have endeavoured to explain these bodies as resulting from irritation of a non-specific kind. But Hückel, whilst not admitting their parasitic nature, has been led to infer that they are the result of some alteration of the cell produced by the parasite or its toxin. E. Pfeiffer has shown that lymph that has lost its activity through filtration or otherwise, is incapable of producing "bodies" in the corneal epithelium. Wasielowski has propagated the vaccine virus on the rabbits' cornea for forty-three generations, and used the corneal epithelium scraped off the forty-third consecutive rabbit for vaccinating children, and produced a large percentage of typical vesicles. The only feature presented by such virulent epithelium and not presented under any circumstances, by normal or otherwise irritated epithelium, is the presence of the "bodies" described by Guarnieri. For this reason it was difficult to escape from the conclusion that the "bodies" were the carriers of the infection. The cycle of development which they went through was far from being clear. In some form or other they must exist in vaccine lymph. Perhaps this was what Cohn described as *Microsphaera vaccinae*. Perhaps some of the "cocci" found in fresh lymph were really stages of this mysterious protozoon. Beyond the seeming existence of a nucleus, the most careful examination had failed to reveal much structure in the "bodies" as found in the infected epithelium, and as to their reproduction and developmental cycle we know little or nothing. Through the kindness of Dr. Gustave

Mann, of the Physiological Laboratory, Oxford, who had carried out a thorough investigation of the histology of the vaccine process, he was enabled to show the several stages in the evolution of the vaccine vesicle, illustrated by lantern slides and actual preparations, and he also exhibited slides and sections of the inoculated rabbit cornea in which every cell was seen to harbour one or more "bodies." He (the speaker) had lately seen a statement that Guarnieri had been able quite recently to cultivate his organism within collodion sacs in the peritoneum of the rabbit, but was unaware whether the fact had received confirmation.

Dr. MONTGOMERY held that we never had a vaccine pustule—the pustule was the result of want of cleanliness. Pure lymph gives vesicles only. He would like to hear from Dr. McWeeney if he had ever found these Guarnieri bodies in lymph supplied to the Cow-pox Institution? Could these bodies be cultivated and vaccination be produced from the cultures?

Dr. McWEENEY declared he was at one with Dr. Montgomery in saying that pure lymph never produces a pustule. He had not as yet commenced a systematic search for the bodies.

Dr. McWeeney here resumed the chair.

Dr. J. P. DOYLE read his paper, "Disease of Two Upper Cervical Vertebrae and Upper Part of Left Humerus." The patient, a boy, æt. 9, was admitted to St. Joseph's Hospital, under Dr. Doyle's care, on September 6th, 1901. He was suffering from a pain in the left shoulder joint. The boy stated that he fell from a ladder on a large stone, a distance of 20 ft. He was found to have a temperature of 100°, and he complained of pain in the joint, and was noticed to carry his head to the left side. On the 28th of the same month the pain was acute, and his limbs were stiff. On October 8th Dr. Doyle excised the head of the humerus. The boy made a good recovery, and the wound healed by first intention. On October 23rd the temperature of the boy rose to 104°, but some days before death it fell to 97°. He looked on the case as one of osteomyelitis. On December 4th, at night, soon after a nurse had been with him, the boy died suddenly. At the autopsy, Dr. Doyle found the anterior surface of the occipital bone and first and second cervical vertebrae with their intermediate anterior portion very much eroded. The odontoid process of the axis considerably diseased, especially the left side, and it protruded through the atlas in a very oblique direction. By the giving way of the transverse ligament the process pressed on the upper portion of the spinal cord, and thus caused sudden death. The atlas is displaced slightly downwards to the left side, owing to the articular surfaces on that side being much eaten away. And in this position there can be seen the remains of the sinus in the soft tissues which burrowed down to the acromial end of the clavicle. The pancreas was found enlarged and hard, all the viscera were anæmic but otherwise normal.

Dr. McWEENEY thought that the case more resembled one of tuberculosis than of osteomyelitis, of which it would be a very rare example.

Dr. MONTGOMERY moved, and Dr. WATSON seconded, that Dr. Doyle's paper be sent to the Reference Committee, which was adopted.

CORK MEDICAL AND SURGICAL SOCIETY.

At a Special Meeting of this Society, held in the Cork Assembly Rooms on Monday, January 13th, the President, Dr. T. GELSTON ATKINS, in the chair, Dr. MACNAUGHTON-JONES delivered a lecture on "A Critical Analysis of Some Recent Gynecological Methods," an abstract of which appears elsewhere in our columns.

Dr. NATHANIEL HOBART, Consulting Surgeon to the Cork North Infirmary, and Dr. P. J. CREKEN, Consulting Physician to the South Infirmary and County Hospital respectively, proposed and seconded the vote of thanks which was passed to the lecturer, who received a most hearty welcome from a number of old friends and senior students of the Queen's College who were present.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 19th, 1902.

PHLEBITIS OF THE MESENTERY VEIN.

At the meeting of the Société de Chirurgie, M. Picqué related two cases of thrombo-phlebitis of the mesentery vein with gangrene of the intestine. The affection was rare, as up to the present only twelve cases were reported.

The first case was that of a man who, after twenty days of diarrhoea and three days of constipation, passed bloody stools, necessitating an immediate operation. The house surgeon performed laparotomy and explored the region, but finding nothing of note, established an artificial anus. The man died in a few hours, and the autopsy revealed the existence of a thrombo-phlebitis of the mesentery vein accompanied by gangrene of the intestine.

In the case of the second patient, the speaker thought right to diagnose a volvulus of the sigmoid flexure. Laparotomy showed gangrene of the intestine, and there was no strangulation. The post-mortem revealed the same facts as in the preceding case.

M. Quenu thought the phlebitis, instead of being the primary cause, was consecutive to the gangrene of the intestine. He regretted that a bacteriological examination had not been made.

GANGRENE PROVOKED BY PROLONGED TAXIS.

M. Guinard read a paper on a case of strangulated hernia, complicated with sphacelus after reduction by prolonged taxis.

The patient was brought to the hospital in a very grave condition, and believing that it was a case of reduction *en masse* of the strangulated hernia, the surgeon performed laparotomy. When the loop was brought to view a perforation was found, which, however, was quickly sutured, and the man recovered. The case proved once more the danger of prolonged taxis.

INCOERCIBLE VOMITING OF PREGNANCY.

Prof. Condamin, of Lyons, had some time ago the occasion of observing a young pregnant woman who, not able for three weeks to support any food, was reduced to an advanced state of cachexia, with threatening cerebral trouble. Artificial abortion seemed to be absolutely necessary, but, considering the condition of the patient, the operation was deferred until some effort was made to get up her strength. For this purpose enemata, frequently repeated, of artificial serum were ordered daily. Twenty-four hours after the first injections, the patient recovered consciousness, and towards the sixth day the condition was so much improved that the intention of provoking abortion was abandoned. Five days later the patient was able to take nourishment, and gradually she returned to health.

With this example before his eyes, and considering that the incoercible vomiting of pregnancy might be depending on a general intoxication of the organism as had been found in the case of eclampsia, M. Condamin decided to treat in a systematic manner such cases by means of artificial serum injected through the rectum at the daily dose of three or four quarts, divided up into enemata of ten ounces each. In order that those clysters be well borne, the liquid should be warm and

the injection practised very slowly (time, ten to fifteen minutes).

In case of intolerance, a few drops of laudanum might be added, or recourse might be had to the hypodermic method.

The treatment should last ten days during which the patient should receive no nourishment, either solid or liquid. After this lapse of time the patient can commence to take some liquid and gradually returns to the ordinary aliments. The injections of artificial serum should be prolonged for a few days.

M. Condamin treated in this way eight cases without ever having to resort to abortion.

RHEUMATIC ARTHRITIS.

The following will be found useful in allaying the pain of this cruel affection:—

Salicylate of methyl, 3iv ;

Chloroform, 3ij ;

Menthol, xxx grs. ;

Lanoline, 3ij.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 18th, 1902.

"WRATSCH," 43/1901, contains an article on the

TREATMENT OF EPILEPSY,

by Dr. M. Livin, in which the author claims to have obtained results incomparably better than those obtained by any other method. The treatment consists in a diet poor in sodium chloride, and the administration of sodium bromide and opocerebrin. The psychical symptoms are said to disappear quickly, the attacks gradually become less frequent, and occasionally cease altogether. By longer continuance of the treatment even obstinate cases of long standing may be cured. The more frequent and severe the attacks, the longer they have existed, the more strictly must the bromide diet be carried out, and in any case for a period of not less than three months. The opocerebrin must be carried out also, with occasional interruptions until the cure is complete. The daily dose of the bromide must be 2 to 3 grammes, and in bad cases this must be increased. The opocerebrin was given in daily doses of from 0.2 to 0.6 grm. No unpleasant effects were observed as the result of the treatment in any case.

The *Munch. Med. Woch.*, 47/1901, contains an article on the

TREATMENT OF ANTHRAX BY COLLARGOLUM,

by Dr. Fischer, Dresden. Collargolum is the name for a soluble form of silver introduced by Credé the younger, of Dresden. The patient on whom the remedy was tried had had for three days a large anthrax carbuncle that occupied the whole right half of the face. He had had a number of rigors, high fever, a very bad general condition and difficulty of swallowing. No immediate operation was performed, but in place of this an intravenous injection was made of 5 c.c.m. of a one per cent. solution of collargol. Even after the first injection the condition improved in a few hours, but only to become worse than before. After the second injection the improvement lasted longer, and after the fourth the condition had become normal. One injection was made daily. It was remarkable that no necrosis took place, the board-like hardness gradually softened, and

after fourteen days only a small superficial scab was cast off. Anthrax bacilli were repeatedly found in the carbuncle and in the blood. No other treatment was carried out. The case appeared to be hopeless, and the remarkable and rapid improvement after the intravenous injection could only be attributed to it. No disagreeable by-effects were observed.

EXTENSIVE RESECTION OF ABDOMINAL WALLS AND BLADDER.

Wratsch, 39/1901, contains a case reported by Dr. Herzen. The patient was a woman, æt. 26, who was admitted into hospital with pain and tumour in the lower part of the abdomen. The symptoms came on after confinement three months previously, and the tumour occupied the whole of the left hypogastrium. The tumour was ovoid, firm, with a smooth surface and painless. Its margins were one finger-breadth above the umbilicus on the right, one and a-half finger-breadths beyond the middle line, and downwards below the symphysis. The abdominal wall was opened at the external margin of the rectus from the umbilicus to the pubes. The muscle was drawn towards the middle line, when it was seen that the posterior surface of the muscle was attached to the tumour. The finger introduced into the abdomen showed that the tumour tilted towards the pelvis, and that it lay within the thickness of the abdominal wall. The left ovary, the size of a hen's egg, was firmly attached to the abdominal wall. The tumour, along with the peritoneum, was removed, also the Fallopian tubes, the round ligaments, and the upper part of the broad ligaments and the ovaries. In the *cavum Retzii* the tumour was attached to the bladder wall. This was opened and removed in part. The bladder was then sutured in two layers, and interrupted sutures were used for the peritoneum. In the abdominal wall was a deficiency over which the remains of the rectus muscle with its aponeurosis was drawn by suture. Continuous suture was used superficially, and an opening was left in the lower angle of the wound. Through this gauze was introduced into Douglas' pouch. The bladder was emptied every four hours. Recovery was uninterrupted. The fistula closed on the tenth day, and the bladder was emptied spontaneously from the sixth. By the cystoscope a long, contracted, straight cicatrix was seen. In the substance of the ovary a space filled with a creamy fluid was found, the space communicating with one in the tumour of the abdominal wall. Microscopic examination showed a fibrous reticular framework, with numerous round and spindle cells with small and large vessels like nuclei. In places the structure was purely fibrous.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Jan. 18th, 1902.

CIRRHOSIS CARDICA.

At the "Gesellschaft" Eisenmenger read a paper on the oft-discussed subject of cirrhosis of the liver due to cardiac affections. After long and careful consideration he is inclined to believe that the condition is not one likely to arise from the degree of hepatic congestion caused by cardiac incompetency. Microscopic examination of the liver of patients who have suffered from congestion of this nature show that the veins become

greatly distended and even destroyed, indeed a whole lobe of the liver may share the same fate, but there is never the increase of fibrous tissue which is present in cirrhosis. The usual changes present in the liver from uncompensated valvular disease are reduction by solution of continuity, irregularity of its surface, or the whole structure becomes granular and friable, but the hardening of the fibrous tissue never. The ætiology of cirrhosis must therefore be due to another cause. Although many of the physical signs are common to both, the diminution of the liver in congestion is due to atrophy of the parenchyma, with increase of the inter-cellular tissue, which does not harden or cause pericholangitis or periarteritis, such as lead to the pronounced consolidation of cirrhosis.

The multiple irregularities on the surface of the liver are likewise explained by emboli in the veins, which seal up the outlet forcing the fluid back on the points of least resistance. The cases recorded in the literature of the subject, where cirrhosis is assumed to be due to the want of cardiac compensation are where cirrhosis has incidentally been associated with cardiac lesions. The parenchyma is reduced in congestion, but the fibrous tissue of the vessels is greatly thickened, and may lead to error, by association with genuine cirrhosis.

When emboli form, the surface of the organ becomes irregular, which may ultimately be changed by cardiac compensation and regeneration.

Genuine cirrhosis depends on alcoholic abuse, which may have been far advanced when the cardiac lesion occurred, and thus lead to an association of morbid features.

GASTRIC ATONY.

Pick defined this morbid condition as a reduction in the muscular tonus of the stomach. The motility of the organ consists of a peristaltic action as well as of circular contractions, or, in other words, an action forwards as well as a circular movement by which the food is churned in the interior, so that the entire surface of the bolus may become exposed to the action of the gastric juice while the longitudinal fibres by their contractions drive it forwards into the duodenum. The atony therefore affects the internal muscles of the organ in the first place, and interferes with the regular emptying into the bowel before it undergoes decomposition or determines some other disturbance.

In the classification of these diseases Stiller has grouped neurasthenia, dyspepsia and enteroptosis as closely allied to the same group, and for these he has substituted the comprehensive term of *asthenia universalis congenita*, and from the name it is evident that he considers it to be transmissible as *costa decima fluctans*, or the floating tenth rib.

The acquired form is either catarrhal or nervous in origin. In both cases the terminal vagus, or splanchnic nerves are affected either by chlorosis, anæmia, or some acute affection. Overloading the stomach is another very fruitful cause of atony, which frequently leads to megalo gastria, as met with in vegetable eaters, who invariably take large quantities of this food. The consequence of this atony is a flabby state of the bowel, rapid emaciation of the organs, atrophy of the musculi recti, hernia at the umbilicus, with a general reduction of the intra-abdominal pressure.

Ectasia or dilatation is more than a functional disturbance of a temporary nature, although it is due to a reduction in the tonus of the muscles as well as a hypertonic of others, which prevent an emptying in the bowel, thus inducing hypertrophy with dilatation of the organ. This form has also a tendency to recover when the cause of obstruction is removed.

Boas favoured the division into motor insufficiency of the first and second degrees, according as the contents of the stomach were fully or partially discharged. The fallacy in this classification lay in the fact of atony being present which was not due to motor insufficiency.

The subjective symptoms of atony are belching flatus, feeling of fulness, and hyperæsthesia. Trousseau laid great stress on the symptom of vertigo, which he considered pathognomonic, and which he designated *vertigo e stomacho laeso*. Diffuse, local or frontal headaches, or hemicrania may be recognised as characteristic harbingers of the disease. Arrhythmia, bradycardia, and tachycardia, with a nervous depressed state, are all characteristic phenomena.

To prevent early auto-toxic effects he recommends early washing of the stomach with a 0.05 per cent. solution of creosote, or 0.1-0.2 solution of ammon. sulpho-ichthyol three times a day.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

FOREIGN BODY AT THE BASE OF THE SKULL.—Mr. PEYTON BEALE operated on a boy, æt. about 6, who had been admitted and found to be suffering as follows: He was looking extremely ill, and had a very offensive discharge from the right ear; behind and below the region of the right mastoid process there was a large fluctuating swelling, evidently an acute abscess surrounded by a considerable area of œdema; there was also considerable pain in the neck, intensified on pressure in the region of the internal jugular vein, and some pain behind the sterno-mastoid as well, but no enlarged glands could be felt in these regions. The child's temperature was over 103°, and the pulse was too rapid to be counted. The history of the illness was: fourteen days previously the boy complained of pain in and behind the ear; this went on for five or six days, when a profuse discharge tinged with blood was observed issuing from the meatus. The swelling behind the ear had only appeared three days prior to admission and had increased very rapidly, but the general condition of the boy had been good until the day before his being brought to the hospital. The case was of course diagnosed by the house surgeon as one of acute mastoid, probably extending to the lateral sinus and the internal jugular vein. In the absence of the aural surgeons Mr. Beale was asked to see the case; the child was thereupon at once admitted and prepared for operation. A vertical incision about two and a-half inches long was made into the fluctuating swelling behind the mastoid process, and a large quantity of very offensive pus evacuated. On inserting the finger it passed downwards and forwards internal to the tip of the mastoid process, and also internal to the styloid process; the internal carotid artery was then felt, and at the same time the rough end of some abnormal structure, which was apparently in close con-

tact with the artery. A pair of sinus forceps was then introduced through the wound, and by its aid a tubular piece of wood, which was found to be about an inch and three-quarters in length and a quarter of an inch in diameter was cautiously pulled out. On again inserting the finger several smaller fragments of wood were discovered, and these were removed by the forceps, and were found to consist of splinters of bamboo, none of them more than an inch in length. The cavity was then thoroughly irrigated, and gently stuffed with iodoform gauze some of which was left projecting from the wound, which was dressed in the ordinary way. The first tubular piece of wood which was removed was found to be a piece of hard bamboo such as is used in making "pan pipes." Mr. Beale said that the only point of interest in the case was to discover how these foreign bodies had reached the position in which they were found at the time of operation: The most careful inquiries were made of the child's mother, and of all the relatives who had come in contact with the boy, but it was found that none of them could give any history of the child having met with an accident at any time, and there was absolutely no evidence to show that the foreign bodies had been forced through the mouth, nose or neck; the only conjecture which remained, therefore was, that they had been forced into the auditory meatus, and through its anterior wall, and so down to the base of the skull. He remarked that there was some little difficulty at first in finding the track leading to these foreign bodies, but after carefully examining the mastoid process it was evident that there was no disease in connection with it, and so the abscess cavity was well explored with the finger in all directions until this track leading forwards and inwards was discovered.

For the next few days after the operation the auditory meatus was frequently irrigated, and it was found not to exhibit any marks of previous injury, and the membrana tympani was normal. The child made an uninterrupted recovery, and was discharged perfectly well and free from pain in about fourteen days.

MIDDLESEX HOSPITAL.

REMOVAL OF FOREIGN BODY FROM THE ŒSOPHAGUS.—Mr. KELLOCK operated, in the out-patient department, on a child, æt. 3, who had been brought to the hospital with a history that three months previously she was stated to have swallowed a half-penny. She was taken to a hospital immediately and the mother was given directions as to how to feed the child, and told that the coin would probably pass *per anum*. It appeared that the mother had not regularly examined the child's stools, so that it was doubtful whether the half-penny had passed or not. As the patient did not seem properly well she was on several occasions taken to a medical man, who repeated the advice given at the hospital. Since the accident the child had shown very few symptoms. She had had occasional pains in the neck and stomach, but they did not seem to have been severe. There was no vomiting, and she had taken food, both liquid and solid, as usual without much discomfort. On examination nothing very definite could be made out; the voice was unaltered, and no swelling or tenderness could be made out about the neck or abdomen, but on examining the child with a screen in a dark room a round dark shadow was at once perceived situated in the

middle line on a level with the upper border of the sternum. An anæsthetic was given, and the girl's mouth being held open with a gag, a coin catcher was passed down the œsophagus, and on the second attempt withdrew with comparative ease an almost black half-penny. Its removal was followed by a little vomiting, and there were a few streaks of blood in the matter brought up. As soon as she had recovered from the anæsthetic she was sent home. Mr. Kellock said the chief point of interest in this case was the length of time the coin had remained fixed in the œsophagus and the few symptoms to which it had given rise. He pointed out that the detection of its position by means of X-rays had settled the question of diagnosis; the foreign body had been fixed in what is by far the most common position for a body of this size to become impacted, namely, opposite the upper border of the sternum. He thought the danger of such an accident consisted in the probability of ulceration taking place round the foreign body; in this case, however, there appeared to have been little or none of this, for the coin was removed with comparative ease, and the bleeding which followed its extraction was insignificant.

MUNICIPAL SANATORIA.

THE figures that represent the average loss from phthisis among civilised communities have a remarkable agreement in all parts of the world where the disease is rife. Roughly speaking, the mortality from that cause reaches a total of about one-seventh of the population. The man in the street now knows that in recent years the whole conditions with regard to the origin and the course of consumption have been more or less completely revolutionised. The individual attacked by that most deadly infection need no longer despair of cure, while the outlook so far as regards prevention has reached a most reassuring and comfortable stage. The duty of administering the practical measures arising from the modern developments both of the preventive and the curative sides of tuberculous

diseases falls mainly upon the local authorities of the United Kingdom. The cost of dealing with vast numbers of phthisical patients would alone prevent any central government from undertaking the task. On the other hand full powers and plastic organisations are already in the possession of the local, sanitary, and Poor-law authorities. The solution of the problem has been already partly attempted by the generosity of the charitable public. The magnitude of the matter, however, renders it impossible to be dealt with by purely philanthropic effort, although hardly any imaginable public system could afford to neglect the substantial service forthcoming from that quarter. At the same time, it may be assumed with a fair amount of confidence that tuberculosis in all its practical aspects must, in the main be left in the hands of the public authorities. Many local authorities have recognised their responsibility in the matter, and have established sanatoria for the treatment of consumptives according to the best modern methods. On the whole, it may be said that a great deal of useful work has been done by these public undertakings. The lesson to be learnt from the experience not only of public but also of private institutions of this nature is most instructive, namely, that they repay expectations in advanced cases of phthisis. The fact of the matter appears to be, if we may say it in so many words, that the public sanatoria should be reserved for the reception of early or "incipient" cases. It is only by a strict limitation of the kind that a fair proportion of the curable cases can be placed under favourable conditions for recovery. When the local authority finds itself in a position to command further hospital accommodation it may then be advantageously used for advanced chronic cases. In that way a great deal of good may be effected by the isolation of numerous centres of infection, while in a few instances cure may be attained. To treat cases without selection in municipal sanatoria is in our opinion to endanger the success of a measure calculated to confer solid and lasting benefits upon the community. Statistics from such an institution might suggest an entirely false conclusion as to the proper place and value of sanatorium treatment in tuberculous disease. Classification of cases, indeed, may not unreasonably be regarded as the key to the future success of public sanatoria in modern communities. That fact cannot be too widely recognised by medical officers of health and others who are interested in the foundation and management of such sanatoria. Indeed no system for the treatment of the consumptive poor can be regarded as complete unless it makes full provision for the accommodation both of incipient and of advanced stages of the disease. The New York Academy of Medicine have paid considerable attention to the wider issues of the subject, and have contributed several suggestions of value. One point which they emphasise is that sanatoria should be conducted in such a way as not to impose undue monetary burdens upon the com-

munity. In view of certain modern public hospital developments in various parts of the United Kingdom it would be well to remind local authorities that there is all the difference in the world between reasonable liberality and unreasonable extravagance. From the circumstances of the case, the public sanatoria have to provide mainly for the poor classes of the community. In many incipient cases, it will actually benefit the patients to do a certain amount of out-door work. As a matter of fact, a substantial return has been made in some of the sanatoria, by way of farm and garden produce consumed by inmates. The whole subject is beset with many interesting points that await further solution, and it is undoubtedly worthy of the most serious and enlightened consideration at the hands of social reformers.

MEDICAL FEES IN LEGAL PROCEEDINGS.

In another column we report the sequel of the case of *Nolan v. the Great Northern Railway Company*, to which we have already alluded in these columns (December 4th, page 611) and which is of considerable interest to the medical profession. The main question, so far as medical men are concerned, dealt with the amount of fees to which a medical witness was entitled for giving evidence in Court. The point at issue was in brief this: The schedule of costs drawn up for the direction of Taxing Masters lays down that for professional witnesses residing within five miles of the place of trial, one guinea a day should be allowed for attendance in Court, unless in the opinion of the Taxing Master, the case was an exceptional one. In *Nolan v. the Great Northern Railway Company*, in which the plaintiff had obtained a verdict, the Taxing Master allowed costs to medical witnesses at the rate of five guineas a day, as he considered the case to be exceptional. The company thereupon submitted that there were no exceptional circumstances to justify any increase of costs. The Court of the King's Bench supported this view, and against their decision the plaintiff appealed. The case will be remembered as the one in which Mr. Justice Wright expressed the "colloquial" opinion that an eminent medical man was one who "drove a brougham and lived in Merrion Square." The point for the Court of Appeal to decide was whether this was an exceptional case or not, and whether, if so, there were special grounds for the increased allowance. The Court was unanimous in considering that it was not an exceptional case and that there were no special grounds for the increased allowance, and that consequently the appeal must fail. The effect of this decision on the future relations under which medical witnesses will go into Court is not at first sight very apparent. It is perfectly obvious that no defeated litigant will ever admit that his adversary's case was a special one. It seems to be equally clear that no Taxing Master will, for the future, regard any case as exceptional,

for, says Lord Justice Fitzgibbon, "it is almost impossible to lay down a hard and fast rule as to what is an exceptional case;" consequently, the Taxing Master will refuse to run the risk of having his award overthrown. It is, however, indisputable that, as Mr. Justice Barton remarked at the first hearing of the case, "one guinea a day is not a reasonable fee for a doctor, between party and party, for attendance in Court." And it is certain that, if litigants require the opinion of medical men of repute and standing, they will not find it possible to obtain it at such a fee. We are inclined to think that perhaps after all the *status quo ante bellum*, so far as the medical profession are concerned, will be maintained. Medical men of eminence are far more likely to refuse to go into Court because they do not care for the worry and anxiety it entails, than they are to lack opportunities of going there at proper fees. Medical fees will in the future, as at the present, have to be paid beforehand. It will be for the solicitor in charge of the case to take care that his own initial expenses will be refunded. This is not a matter which directly concerns the medical profession, and consequently we are of opinion that the decision of the Court of Appeal will not materially affect the relations under which a medical witness goes into Court. There is one other aspect of the question on which we should like to say a word. Mr. Justice Wright, whose prosaic definition of "eminence" we have quoted, further spoke as follows: "Sometimes medical men thought they were engaged in a duel. They remained in Court, listening to the evidence for the claimant with the view of disproving what had been said on the other side. One of the dangers arising from that was that they were apt to forget their character of witnesses to tell the truth, and become advocates of the side employing them." We cannot profess to say to what proportion of cases Mr. Justice Wright's rather vague "sometimes" is meant to apply. A judicial "sometimes" is usually taken by the public to include a large number of cases, and if the speaker meant it to bear this interpretation, we have no hesitation in affirming that he is incorrect. On the other hand, if Mr. Justice Wright did not consider that the evil of which he complained was a widely spread one, he was not justified in referring to it in the terms he did. At the same time, although we question the justice of, and the necessity for, Mr. Justice Wright's remarks as an appendage to a judgment affecting the medical profession generally, we are afraid that we must admit that perhaps in some isolated instances medical men have given their evidence in a manner which is not misrepresented by Mr. Justice Wright's description of medical evidence. Such cases cannot be too sternly criticised by the medical profession themselves. That a medical witness should remain in Court with the object of disproving what another medical witness said, or that a medical witness should forget the character of a witness, is, if true, in direct opposition to the etiquette and practice of the medical

profession. Apart altogether from the fact that no member should lend himself to attempts to discredit the evidence of a brother in the profession, it is his duty to state in Court the truth and nothing but the truth. That the exigencies of *Nisi Prius* practice do not always enable him to tell also the whole truth, does not obliterate the fact that it is his duty to be an impartial witness. If we considered that higher scale fees were demanded on the ground that the duties of a medical witness were, what Mr. Justice Wright says they are considered to be by medical men, we should have no hesitation in condemning them. But they are demanded on no such grounds. Medical men of eminence must be obtained as witnesses, they must be paid the fees which will compensate them for the trouble and time they devote to the case, and if the law of the land prevents the subsequent reimbursement of the solicitor, that is not the business of the medical profession.

VACCINATION.

FROM a small Wiltshire town a local magnate addresses the world through a local Kerry paper on the popular delusion that vaccination has any preventive power against small-pox, or that efficient vaccination can even modify an attack of small-pox. We suppose the author of the letter referred to wishes to gradually bring the truth before the public by allowing it to filter over the United Kingdom, lest a sudden outbreak of the truth, crushing our cherished opinions, might be too much of a shock to us. He takes as his text the number of vaccinated and unvaccinated persons that died in London during the week ending December 14th, 1901, and then flies from his text to relate the story of a young man who died of small-pox in 1892, who had been vaccinated in childhood and twice re-vaccinated, and he goes on to say that in the Registrar's report for that year it is returned under the heading "no statement." Now in the return for the week ending the 14th ultimo, the deaths registered from small-pox are returned, according to the letter, as sixteen vaccinated and seven unvaccinated, and three "no statement." He adds the three to the sixteen, and groups the nineteen deaths as of vaccinated, as against seven unvaccinated, and draws the deduction from these statistics that vaccination is of no value. We would just remind our readers that statistics show that the fatality of small-pox varies (1) with the amount of vaccination possessed by the individual, (2) according to the age of those attacked, (3) according to the quality of the vaccination scars in those attacked. Dr. Gayton found that with four good scars there is an absolute immunity up to the age of fifteen years; with good scars, whether one, two, or three, there is immunity up to the age of five years. When all the good and imperfect vaccinations are grouped together, it shows that from ten to fifteen, and from fifteen to twenty years of age the good vaccination afforded just three times the amount of

protection against death from small-pox that the imperfect vaccination afforded. To ensure protection, re-vaccination is necessary, infantile vaccination is of chief avail in the first five years of life; but its protective power cannot be depended on throughout adult life. In the Sheffield epidemic of small-pox the unvaccinated were attacked, in proportion to their numbers, as twenty to one of those vaccinated. The teaching of experience is that the greatest protection against attack is found near to the operation of primary vaccination or re-vaccination. The greater the remoteness from the date of vaccination the greater has been the incidence of small-pox and the fatality of those attacked. How much vaccination mitigates the subsequent attack of small-pox when it occurs is well shown by the following statistics: In Sweden, under ten years of age, where there was only one visible mark, or one cicatrix only, 75·7 per cent. had discrete or mild attacks and 24 confluent attacks. Where there were two cicatrices, the corresponding figures were 88 and 12. Where there were three cicatrices, 95 and five; where there were four or more cicatrices, 97·5 and two. With these facts before them, we have little doubt but that the belief in the power of vaccination to confer immunity from small-pox for a time, and to mitigate its effects for years after, will continue. We, however, recognise that in every community there are "flat-earth" men who are not amenable to reason.

Notes on Current Topics.

Tobacco and Deafness.

ANY relation between deafness and the use or, rather, the abuse of tobacco is generally due to the irritant effect of the latter on the upper air passages, whereby catarrhal conditions are induced which may spread up the Eustachian tubes to the middle ear. Thus the best explanation for the chronic hardness of hearing sometimes observed by smokers is that it is due to a simple middle-ear catarrh. The possibility of a chronic neuritis of the auditory nerve analogous to tobacco amblyopia, which Moss assumed to be the cause of smokers' deafness and tinnitus aurium, cannot be denied; but, so far, no adequate proof of its occurrence has been placed before us. In the December number of the *Birmingham Medical Review*, however, Stanley published the interesting case of a soldier, invalided home from South Africa for enteric, who, on the voyage home, smoked largely of a coarse, strong twist, the only merit of which appeared to lie in its cheapness. He developed a tobacco heart from this indulgence, and with it complete deafness. Unfortunately, the description of the aural symptoms and examination is very imperfect and inadequate, but the condition was evidently one of internal ear deafness. The patient was told to give up smoking, and when this order had been carried into effect for a month, both heart and hearing were greatly improved. It is unlikely that the deafness can have been due to the enteric

fever, as the labyrinthine complications following that disease are very unfavourable, and are certainly most unlikely to improve without treatment. As far as we can judge, the case must have been one of auditory neuritis due to tobacco poisoning, a condition of such rarity as to make the case referred to of great importance.

Post-Mortem Risks.

A CERTAIN number of members of our profession succumb or are more or less disabled by accidental maladies contracted during the performance of post-mortem examinations. Most of these risks are well known, and can be guarded against with more or less success. We have, however, recently met with a risk which has not, we believe, been described before, viz., that of contracting typhoid fever during an autopsy. This was the unhappy experience of Dr. W. Furnrohr, who related his experience in a recent number of the *Munchener Medicinische Wochenschrift*. He made a post-mortem examination in a case of enteric fever, and about three weeks later noticed the first symptoms of the disease. It seemed perfectly possible to exclude every other source of infection, and the author entertains no doubt that the malady was contracted at, and through the autopsy in question. The greatest precautions were taken by Dr. Furnrohr to disinfect his hands, and it does not seem possible that the infection can have been conveyed in this way. He himself believes that he received the virus through the mouth at the time of the washing out of the intestine by the spurring of water from the hose, and this seems a very plausible explanation. It follows that enteric fever must be added to the list of risks which have to be faced by the pathologist in the execution of his lugubrious task.

The Physician as a Destroying Angel.

THE unlettered public entertain strange ideas as to the rôle of the physician, ideas which find expression, for instance, in the belief that he is in the habit of "suppressing" infant monstrosities at birth. They overlook the fact that the function of the physician is essentially to assuage suffering and to prolong life, a rule to which no exception is possible even when the result may conceivably be detrimental to the race as well as distressing to the individual. It may well be questioned whether the exercise of this function is beneficial either to the community or to the individual when, for instance, medical care enables the tuberculous or constitutionally debile or malformed subject to linger on a melancholy existence and ultimately to reproduce his weakly species, and also when death is postponed in painful cancerous affections. Still it would be unwise to confer, and no physician would consent to exercise, any such discretionary power, thus constituting himself the arbiter of life and death. It is this conception which renders the assistance of medical men at electrocutions so distasteful, the function being one which is altogether foreign to

their mandate. The view that this discretionary power might advantageously be conferred on medical practitioners found expression in a petition which, as we mentioned, was forwarded for presentation to the Second Chamber of the Parliament of Saxony, urging that physicians should be authorised to poison on request persons who are suffering from an incurable disease, and who are desirous of ending a life which is a burden to themselves and to those around them. As the petition traversed the law of the land, the petition committee naturally declined to bring it before Parliament, but the fact is interesting as showing what absurd ideas prevail on the subject.

Tetanus Bacilli in Fullers' Earth.

THE knowledge of the specific microbe that causes tetanus is now adequate and minute enough for most practical purposes. The cardinal fact of the *habitat* of the tetanus bacillus being in earth has furnished the key to the source of infection in a great majority of cases of lock-jaw. Last week the point was forcibly advanced by Mr. Wynne Baxter, the East London Coroner. A baby, six weeks old, the son of a public house manager, was seized with the disease in question, and died shortly afterwards at the London Hospital. The coroner elicited the fact that Fullers' earth was used every day in the case of deceased, but the name of the manufacturers of the article was not forthcoming. He informed the jury that he was anxious to obtain information on the point, owing to the fact that so many cases of the kind had been brought under his notice. He had met with eight or nine cases within as many months, and all came from about the same district. If the facts be as thus stated there could be little difficulty in tracing the bacillus to the specifically contaminated Fullers' earth. A matter of this kind clearly falls within the province of the medical officer of health of the district in which it occurs. Nothing could be simpler, from a bacteriological standpoint, than to detect the tetanus bacillus if present in the powder. Nor could an easier matter than the sterilising of the earth by heat be readily imagined. Possibly the well-recognised cases of infantile tetanus associated with the umbilical abrasion may be explained by infection with this specially prepared earth applied for toilet purposes.

New Views on Syphilis.

IF there be one dogma more than another which may be credited with an irrefragable basis of scientific and clinical proof, that which lays down the essential difference between the soft and the syphilitic chancre might well be accorded that position. In an open letter addressed by Dr. Federn, of Vienna, to Professor Kaposi, the validity of this view is called into question, and the hypothesis advanced by this observer in support of his views is sufficiently novel to merit attention. Dr. Federn holds that there is no fundamental difference between the sore

which remains a purely local manifestation and that which is followed by the characteristic manifestations of syphilis. He maintains that all chancres are of the same nature, and that the only difference between the so-called soft chancre and the sore which is followed by cutaneous and other phenomena is dependent upon the more or less copious suppuration. He remarks that the so-called soft chancre is one which suppurates profusely, whereas in the constitutionally-infective chancre the suppurative process is absent or very scanty. His explanation of the difference in the subsequent history is based on the assumption that when the pyogenic bacillus preponderates over the bacillus of syphilis the latter is destroyed and an issue afforded to the poison, which therefore does not infect the organism. If, on the other hand, the bacillus of syphilis predominates, the poison passes into the system. The practical conclusion which he deduces from this hypothesis is that an attack of syphilis may be aborted by setting up free suppuration in the chancre, but as he has not put this assumption to the test of experience it remains a mere hypothesis. Dr. Federn's views run counter to all received views on the subject, and would seem to be contradicted by the negative result of attempts in the past to prevent syphilitic infection by cauterisation or by the inoculation of the hard chancre with the virus of the soft chancre, a method which was tried many years ago by Rollet and his followers. Moreover, it is a common experience to witness the evolution of the two processes side by side, a chancre commencing as a soft sore only to undergo the characteristic induration later on, and followed by the recognised manifestations of syphilis.

The Transmissibility of Human Tuberculosis to Animals.

AN important contribution to our knowledge of the natural history of the bacillus of human tuberculosis in respect of its influence on animals is contained in an article published in the last number of *La Semaine Médicale* by Dr. de Jong, of Leyden. The researches on which his conclusions are based were practically complete before Koch's famous pronouncement, so they cannot have been influenced by the latter. Having obtained pure cultures of the bacillus of human tuberculosis he injected these into various animals—goat, sheep, horse, dog, ox, and monkey—by the intra-venous method; he found that infection was uniformly produced although comparative experiments carried out with tubercle of bovine origin invariably proved more virulent and more promptly fatal than that of human origin. He is inclined to believe that the bacillus of bovine origin would also prove the more virulent even in regard to man. Conclusive demonstration of the accuracy of this hypothesis could, of course, not be afforded, but experiments carried out on the monkey, selected as being the nearest approach to man available, gave very positive results. His results may be summed

up as follows: the bacillus of human tuberculosis determines infection in the cow as well as in certain other animals, including the monkey. The bacillus of bovine origin is much more active in animals than that of human tuberculosis, and there is no reason to believe that it would prove less so in regard to man. It follows that man, as a cause of the infection of animals, is, in all probability, a less potent factor than is bovine tuberculosis as a cause of infection in human beings.

A New Test for Blood.

A NEW test for blood, suggested by Pertol, is based upon absorption, and its simple and inexpensive nature is a great recommendation. The only "apparatus" required is a square of good blotting paper about the size of a playing card. A small amount of blood is aspirated in a pipette and mixed with water in the proportion of 2.5 cm. to 1 cm. The blotting paper is placed on a sheet of glass and the pipette is placed inverted upon it, held perpendicularly in a small standard just touching the paper. The fluid is slowly absorbed by the paper and forms rings of various hues, the tints and size of the rings being characteristic of the different composition of the blood. Pertol has made some hundreds of these blotting-paper pictures of the blood, and found them invariably identical under the same condition of health and disease. The colour fades in time, but the rings are still perceptible. The clearest pictures were obtained with the blood of new-born infants, which contains a larger proportion of reds than does that of adults. Such a picture treated with dilute hydrochloric acid makes a picture resembling the flower of the narcissus.

Latent Pulmonary Tuberculosis.

THE possibility of latent pulmonary tuberculosis, that is to say, of its unsuspected presence cannot be denied. Many writers have estimated that not one case in fifteen of consumption is diagnosed in an early stage, although Upson has placed a still lower estimate upon the number of early diagnosed instances of the disease. The latter observer found that out of a large number of patients who consulted him for other than lung affections, no less than 197 were the subjects of unsuspected tuberculosis—of these individuals, the following details were given:—Naso-pharyngeal catarrh sixty-eight, hypertrophic rhinitis thirty-nine, hypertrophic tonsils thirty-five, suppurative middle ear disease twenty-five, chronic non-suppurative middle ear disease eighteen, and nasal polypi twelve. In 118 cases there was a rise of temperature of from 0.8° to 1.6° Fahr.; in thirty-eight cases in which the temperature was normal, exercise sufficient to cause fatigue brought about a rise from 0.9° to 1.9°. In seventeen cases the morning temperature was sub-normal. The respiration and the pulse were accelerated in 105 cases. The majority of the cases complained of a general tired feeling in the morning, despite a good night's rest. Slight cough, especially on lying down or on getting up in the morning, was present in 130 cases, and shortness

of breath on exertion was noted in 165 cases. Hæmoptysis occurred in twelve cases. The lesson taught by these facts is an important one, and the main points are applicable to general medical practice. It will be noted that all the cases were the subjects of some nasal, throat, or ear condition, and it would be interesting to know how many of the cases were the victims of adenoids. The work which has been done by various observers upon the relationship between hypertrophy of the pharyngeal tonsil and tuberculosis has shown that some 5 per cent. of the cases of the former are the subjects of the latter condition, and it is undoubted that any cause which promotes inefficiency of nasal respiration, especially when due to enlargement of lymphoid structures, must determine a predisposition to tuberculosis.

Cancer Research.

A WELL thought-out scheme for the promotion of the scientific investigation of cancer has been promulgated by Mr. Henry Morris. It is intended to raise a fund to provide, equip and maintain laboratories to be devoted exclusively to the department of research under the superintendence of a specially qualified director with a paid staff of assistants. The cost is estimated at £2,250 per annum. If the necessary funds are forthcoming there is a good prospect of the study of cancer being placed on a sound basis. Steps will also be taken to co-ordinate the labours of those who are working at the same subject in other parts of the world. There are many points calling for systematic investigation in regard to the etiology of cancer, and one of the first things to be done will be to sift the literature of the subject in order to determine in what direction future efforts may best be made. In view of the widespread interest taken in the subject in all classes of society the success of the movement so far as the contribution of funds goes can hardly be a matter of doubt.

The Intraocular Complications of Beri-Beri.

It is interesting to note that, according to the history of a case recently reported to the Belgium Ophthalmological Society by Coppez, the intraocular complications of beri-beri closely resemble that condition which is labelled "toxic amblyopia." "The usual acuity had been reduced to 1-16, and central scotomata for red and green, as well as partially for yellow and blue, were present. Colour perception was normal when tested by Holmgren's test. The peripheral fields of vision were normal. Ophthalmoscopic examination showed hyperæmia of the papillæ, full and distended renal veins, the condition as a whole being a partial retrolbulbar neuritis, with participation of the macula. Diaphoresis, potassium iodide, strychnine hypodermically and abstinence from tobacco resulted in gradual improvement with a restoration of usual acuity to 1-6. It has been observed in Brazil, that oculo-motor palsies, nystagmus and blindness which result from beri-beri may be cured by change of climate and the disappearance of beri-beri. This in itself (says the *Philadelphia Medical Journal*)

"should be an incentive to neuro-pathologists to investigate the structural changes occurring in the optic nerve in beri-beri, and if possible, determine whether and to what extent the papillo-macular bundles are involved.

Unqualified Vaccinators.

It is stated that advantage is being taken by unqualified persons, of the present demand for revaccination to perform the operation on a large scale in certain parts of the metropolis, and a correspondent appeals to us to state whether there are any means of checking this usurpation of medical functions. Obviously, where a certificate of successful vaccination is required the unqualified practitioner would be unable to give it, but in the matter of revaccination he is under no such disadvantage. If people deliberately elect to be revaccinated by the man in the street there is no law to prevent their doing so. It is possible that vaccination by an unqualified person might be held to constitute an infringement of the Apothecaries Act, but in the absence of any false representations as to his professional status we are not sanguine that such proceedings would be successful in view of the curious reluctance of magistrates to construe that Act in a comprehensive spirit. Nevertheless, should any serious results follow this unqualified vaccination, the delinquent would incur serious risk under the criminal law.

The Cost of an Epidemic.

IN certain organs of the daily press, not those of the highest repute, the fees earned by practitioners for revaccination are, with execrable taste, alleged as an explanation of the unanimity of the medical profession on the question of vaccination. It will shortly be brought home to the public that the expense of vaccination is a very trifling matter compared with that of an epidemic of small-pox. Already the Metropolitan Asylums Board stands committed to an expenditure of between £250,000 and £300,000, which represents an increase in the rates equal to one penny in the pound for the next six months, to be followed by another penny in the succeeding period. Before we have done with the present epidemic the expense will run into many hundreds of thousands more, and the public will have an object lesson in the ultimate economy of the policy of universal vaccination.

THE governors of the Macclesfield Infirmary have passed the resolution conceding to the honorary medical staff the right to nominate the candidates to the junior posts at this institution, and this regrettable dispute comes to an end without any likelihood of its recurrence. The principle involved is one which should be adopted at every hospital and infirmary. It is stated that Miss Murdoch Clarke, the innocent cause of the trouble, will vacate her post in the course of a few days, and, as might be anticipated after this huge advertisement, contemplates starting in practice on the field of her struggle.

Observations on Decapitation.

ALMOST ever since decapitation became an orthodox form of execution, men of science have from time to time occupied themselves with speculations on the question of the possibility of sensation and thought remaining for a space in the severed head. During the great French revolution, when *La Mère Guillotine* was responsible for so many decapitations, we believe that some individuals even went so far as to experiment with the victims of the Terror. The subject has also, as might justly be expected, crept into fiction, and more than one romance has been the outcome. A surgeon of the United States Navy has recently communicated some interesting observations gleaned by closely watching the beheading of thirty-six Chinese criminals in Canton. These observations impressed him with the idea that death was not instantaneous, but that it came almost immediately after the sword stroke, and was due to syncope. From his description the work seems to have been done very cleanly, as thirty-three of the heads fell at one stroke. The interesting features noted were that in many cases a decided effort to swallow was shown by the expression of the mouth, and the movement and downward bulging of the throat were repeated two or three times; in several cases (judging by the labial movements) attempts were made to articulate in a deliberate manner; the faces showed a momentary look of surprise and intelligence as they fell, with a natural movement of the eyes, as if looking, and an opening and closing of the lids. No convulsive movements of the bodies or limbs took place, the hæmorrhage from the trunks was tremendous, but no spurting took place from the heads. A close examination of the facial expression impressed the observer with the idea that the faces were those of persons in syncope.

The Wearing of Corsets.

PROTESTS have from time to time been made by the profession against the wearing of the modern corset, inveighing against the injury to health which may arise from the custom. Recently, however, Marechal, a French doctor with a tinge of fanaticism, has suggested a somewhat drastic remedy. He asserts that out of every hundred women who wear stays, some thirty only retain perfect health, and he advocates the passing of a law the three articles of which are as follows:—1. Any woman under thirty shall be forbidden to wear a corset of any kind. Any woman transgressing in this respect shall be punished by three months' imprisonment, or if a minor, her parents or guardians to be condemned to pay a fine of from 100 to 1,000 francs. 2. Any woman over thirty may wear any corset she chooses. The third article surrounds the manufacture and sale of corsets with the most rigorous formalities. Those licensed to sell these articles of attire shall be obliged to enter in a special book the name, address, and age of every buyer, neglect of which precaution shall be punishable by fine and confiscation of business. Marechal, if not a fanatic, must be of a

somewhat waggish turn of mind. We should like to hear the opinions of the Parisian ladies of fashion as to his proposed measure.

A Parasite in the Blood of Epileptics.

THERE have been several startling additions to medical science recorded in Paris of late. M. Doyen has discovered a bacterium which is the causal agent of cancer. Another medical man has hit upon a therapeusis which will cure (?) cancer. Now we learn that still another, M. Bra, has found a parasite in the blood of epileptics (a). M. Bra, who laid his discovery before the Académie des Sciences, says that he has examined the blood of seventy epileptics, and that he has found—apparently in all—a micro-organism formed by very small particles which is one micro-millimetre in diameter. It is found singly, as a diplococcus, or in chains. The streptococcus can be stained easily by aniline dyes, but not so well by Gram's method. It thrives readily on various media—bouillon, gelatine, or potato—and can be found under different aspects in the blood of a rabbit into whose veins pure cultures have been injected. The report before us does not state that M. Bra has determined that there is any causal relationship between the bacterium he has discovered and the epileptic attacks. It limits itself to stating that the bacterium has been discovered either during or immediately after epileptic attacks. It is very difficult to imagine a bacterial cause for epilepsy, as the disease possesses few, if any characteristics in common with other diseases which have been proved to be bacterial in origin. It will be interesting to note the further development of this latest Parisian sensation.

Opening of a New Children's Ward.

THE Governors of Mercer's hospital opened a valuable addition to the Hospital, in the form of a children's ward, on January 11th. The opening was made the occasion of a large public function, at which many members of the medical profession and the public took part. Lord Justice Fitzgibbon, a prominent member of the Board of Governors, took the chair, and on Lady Arnott devolved the pleasant duty of declaring the new ward open. Several speeches followed from members of the medical and surgical staff and of the Board of Governors, and among others Mr. T. W. Russell, M.P., spoke. It is interesting to note that Mercer's Hospital is one of the oldest, if not the oldest, hospital in Dublin. It has been in the past associated with many remarkable men, not the least of whom was the celebrated Handel, and one of the first performances of his great oratorio—the "Messiah"—was performed for its benefit.

THE death is announced of Dr. Wordsworth-Poole, Physician to the British Legation at Peking, after a four weeks' illness from typhoid fever. The deceased gentleman was in Peking during the famous siege, and was warmly commended by Sir Claude MacDonald in his report on the siege of the Legations.

(a) *Semaine Médicale*, January 15th.

Small-pox in London.

LAST week's returns showed a marked fall in the number of cases of small-pox reported within the metropolitan area, although on Saturday, the 18th inst., the total number of cases under treatment at the Asylums Board's hospitals touched the highest point yet recorded—909 cases. Judging from former experiences, it would be premature to hope that the decrease represents anything but a temporary lull in the spread of the outbreak. The most likely course of the epidemic will register an upward curve until the summer months are reached, when a steady diminution may be expected. Several interesting facts have come to light within the past week. One of the crew of the 'Alpha,' the fire-ship engaged in extinguishing the recent fire on the Thames small-pox hospital ship, developed the disease. It has been announced officially that altogether no less than twenty-one persons engaged as public disinfectors and inspectors have been admitted to hospital suffering from small-pox, and that in every case the sufferers had not been properly vaccinated and re-vaccinated. Gross carelessness such as this on the part of the Borough Councils seems to emphasise the hopelessness of looking for a thorough administration of the Vaccination Acts by local sanitary authorities. One of the interesting lessons to be gathered from the history of the present invasion is the need of some plan for the systematic inspection of laundries. In several instances the disease has been contracted by the girl whose duty has been to sort out the linen of customers, and the patient has then become a centre of infection both to her fellow-workpeople and her friends at home. Fortunately the process of washing efficiently disinfects the linen, which is then safe unless it is redistributed by the originally infected sorter, or delivered by a carter who has contracted the disease. The greatest danger has hitherto lain in the confusion of small-pox with chicken-pox. There is a good deal to be said in favour of the sanitary authorities that have adopted the compulsory notification of chicken-pox as a temporary measure. Many of the general and special hospitals have closed their wards to visitors, except in cases of especial gravity. It is not a little remarkable that the Asylums Board not only do not forbid visitors to the small-pox ships, but do not even make recent vaccination or re-vaccination a compulsory condition of such a visit. Every week reports come of fresh outbreaks of the disease in towns at varying distances from the metropolis.

Needless Laparotomies.

In the dark days of gynaecology, authors devoted much space and attention to "phantom tumours," and students were sternly warned to beware of these Wills-o'-the-wisp. The routine resort to anaesthesia as a means of arriving at a diagnosis has to a great extent obviated this source of error, and nowadays we hear little of them. If they would be candid, however, operative gynaecologists might materially

aid in bringing our knowledge of this condition up to date. It is well known that in a certain number of exploratory laparotomies no obvious lesion is discoverable, and surgeons calmly accept this negative result on the ground that the opportunity which an exploratory operation affords of distinguishing between real and apparent tumours is the very *raison d'être* of the operation. Practitioners of the expectant class urge, on the other hand, that it is the duty of the operator to consider very carefully whether the risk of death from abdominal symptoms due to unknown causes, is, or is not, greater than the risk of operation; and they make this the basis of an argument in favour of postponing all operative interference until the physical signs permit of an approximately certain diagnosis. To make this our rule of conduct would but stay the hand of the surgeon in precisely the class of cases where operative treatment must be early to be successful, and the risk of occasionally cutting down on a phantom tumour is a bogey which will not deter the modern surgeon from taking the first opportunity of drawing the veil aside.

Arsenical Beer Poisoning at Halifax.

A CONSIDERABLE degree of excitement has been aroused in Halifax by the alleged recurrence of cases of arsenical beer poisoning in that town. The diagnosis has been made by the house surgeon at the Halifax Infirmary, Dr. J. F. Hodgson, who formerly had no less than sixty cases of a similar nature under his care at the Manchester Infirmary. He has thus had a considerable special experience in this form of symptomatic disease, and his opinion that four patients are undoubtedly suffering from arsenical beer poisoning must be accepted as more than probably correct. In two of the cases the men of their own accord left off drinking beer because they became sick whenever they drank a glass of that beverage. The question will, no doubt, speedily be settled one way or the other by chemical analysis, which under improved modern methods is capable of detecting the presence of minute quantities of arsenic in beer with absolute accuracy. It seems almost incredible that the brewery chemists, in view of their recent unhappy experiences, can have allowed arsenical beer to pass through their hands without detection. Possibly, should the present Halifax cases be traced to contaminated beer it may be found that some old stock has escaped notice. In any case there must be culpable negligence nowadays, on the part of some one concerned in the production or the distribution of beer that contains arsenic. It would be interesting to learn what steps have been taken by the medical officers of Manchester and other towns concerned in the late epidemic to prevent a recurrence of the disaster.

PERSONAL.

DR. C. I. PRITCHETT has been appointed Medical Officer to the St. William's Hospital at Chatham, at an approximate salary of £300 per annum.

DR. ARTHUR MOLYNEUX JACKSON has been appointed Medical Superintendent to the Notts County Asylum, vice Dr. Alfred Aplin, deceased.

MR. H. G. PLIMMER, Lecturer on Pathology and Bacteriology at St. Mary's Hospital, has been placed on the Cancer Investigation Committee recently appointed by the German Government.

MR. RUSHTON PARKER, F.R.C.S., Professor of Surgery in University College, Liverpool, Surgeon to the Royal Infirmary, has been elected President of the Liverpool Medical Institution.

At the moment of going to press we have received the welcome news from our correspondent that Professor Virchow is progressing slowly but surely towards convalescence after his recent serious accident.

COLONEL W. L. GUBBINS, Royal Army Medical Corps, formerly Assistant Director of the Army Medical Service, and lately serving in South Africa, has been appointed Principal Medical Officer of the Home District.

DR. J. HALLIDAY CROOM, Consulting Gynaecologist to the Edinburgh Royal Infirmary, Examiner in Midwifery, Royal College of Physicians, Edinburgh, and St. Andrew's University, has been elected President of the British Gynaecological Society.

SIR W. O. DAGLEISH has contributed the sum of £10,000, in response to the appeal of the authorities of St. Andrews for financial assistance. Half the sum is to be devoted to the erection of the new medical school and the remainder to the extinction of the debt.

MR. MYERS, of Birmingham, has founded and endowed a travelling studentship in the University of Birmingham in memory of his son, Dr. Walter Myers, who died of yellow fever when engaged on an investigation into that disease under the auspices of the Liverpool School of Tropical Medicine.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE CARNEGIE TRUST.

At a meeting of the Executive Committee of the Carnegie Trustees, under the chairmanship of Lord Elgin, the reports of the secretary and treasurer up to December 31st, 1901, were presented. The number of students who have availed themselves of the benefits of the Trust was 2,441, and the amount expended on fees was £22,941 16s. 6d., an average of close on £9 per student. If it be true that the fund has not been taken advantage of in this, its first year, to the full extent that is probable in the future, for the reason that many would-be applicants have been debarred from its benefits through not having passed the required preliminary examination, the fear may be expressed that the £25,000 allotted for the payment of fees will scarcely, under the present open-handed system, do more than meet the demand, if, indeed, it does not prove inadequate. The annual meeting of the trustees is to be held in London, and after it the annual report will probably be made public. It need not be said that its appearance is awaited with interest, since hitherto all the statements as to details of the working of the Trust have been more or less speculative, and the public are quite in the dark in so far as any definite knowledge on the subject is concerned.

CRUSADE AGAINST CONSUMPTION.

The treatment of consumption in special hospitals is

a necessary corollary of the disinclination now generally manifest to admit cases of phthisis to general medical wards. It is, therefore, most gratifying to learn that the subject is under the consideration of the directors of the Aberdeen Royal Infirmary, an institution which has recently been relieved of an annual burden of some £800 in the shape of interest by Lord Mount-Stephen's generous gift of £25,000 to free it from debt. Although no public pronouncement has been made, the suggestion is that a consumption hospital should be erected on the ground belonging to the convalescent Hospital at Pitfodels, which is regarded as in every way a desirable site. It is thought that the administrative part of the work might be carried on from the Convalescent Hospital at comparatively small expense.

DR. JAMES ERSKINE, one of the promoters of the Glasgow branch of the National Association for dealing with consumption, delivered a lecture on the subject on 8th January. It was pointed out that while 1,500 persons had died of pulmonary tuberculosis in Glasgow during the year 1901, yet that this was a death rate which had been greatly lowered by the general sanitary reforms of the last thirty years. The Corporation has already adopted some special means for obtaining information as to the prevalence of tuberculosis; circulars had been sent out to all public institutions requesting information of all cases of phthisis, and similar information was got by the bacteriological examination of sputa sent in for report by medical practitioners, as well as through the sanitary department, who were called to disinfect apartments occupied by consumptive patients. But information thus obtained was necessarily incomplete, and compulsory notification was strenuously advocated by the speaker. All cases discovered could then be kept under medical supervision, either by ordinary practitioners or parochial medical officers, &c. Secondly, accommodation for the consumptive poor was urgently required, and the City Parish Council was making provision for 100 such patients in their new hospital at Stobhill. Dr. Erskine also thought that the Corporation should make provision for the treatment of consumptives in an advanced stage of the disease, who were a source of danger, but who were not suitable cases for admission to the parish hospital.

GLASGOW PORT SANITARY AUTHORITY AND PLAGUE.

On account of the recent outbreaks of plague and small-pox in Glasgow, which many consider were imported by seamen, the Corporation of Glasgow has applied to the Local Government Board to be constituted the Port Sanitary Authority for the Customs Port of Glasgow, with a boarding station at Greenock.

BEQUESTS TO EDINBURGH MEDICAL CHARITIES.

By his will the late Mr. J. J. Ford, of Grosvenor Crescent, London, makes the following large bequests:—To the Edinburgh Royal Infirmary, £4,000; the Leith Hospital, £4,000; the Royal Hospital for Sick Children, £1,000; and the Queen Victoria Jubilee Institute for Nurses (Scottish Branch), £1,000.

A Medico-Legal Case.

THE TAXATION OF MEDICAL FEES IN LEGAL CASES.

LAST week, in the Court of Appeal, before Lord Justice Fitzgibbon, Lord Justice Walker, and Lord Justice Holmes, the appeal in the case of *Nolan v. Great Northern Railway Company* came on for hearing. The plaintiff sought damages for personal injuries sustained by the plaintiff by reason of the negligence of the defendants' servants at one of their stations. The case was tried before the Lord Chief Justice and a special jury in January last year, when the plaintiff was awarded £450. Subsequently the costs were taxed, and the railway company objected to certain allowances made by the Taxing Master, in respect of the attendance of medical witnesses, as already reported in these columns. In the King's Bench counsel for the railway company contended that Dr. Morrison, Dundalk, who attended the plaintiff after the injuries

until he was removed to a Dublin hospital, should not be allowed for three separate attendances at Dublin before the trial in order that he might be present at the examination of the plaintiff by the doctors for the railway company. For each of these visits he claimed five guineas. The railway company contended that these charges were unreasonable as the visits were altogether unnecessary, the plaintiff being at the time in the hands of skilled doctors in Dublin who were called, and who gave evidence on behalf of the plaintiff. Surgeon Myles and Dr. O'Carroll had also been called as witnesses for the plaintiff, and the Taxing Master had allowed these gentlemen five guineas a day for their attendance in Court during the trial. The railway company objected to these charges, and relied upon the schedule of costs by which, they submitted, the Master was bound. That schedule provided that for professional witnesses residing within five miles of Dublin only one guinea a day should be allowed for attendance in Court, unless, in the opinion of the Taxing Master, the case was an exceptional one. The company submitted that in the present case there were no special or exceptional circumstances to justify any increase on the scale allowance. In giving the judgment of the King's Bench, Mr. Justice Kenny was of opinion the Court was bound by the schedule and the decision of the Master of the Rolls in *Maconchy v. the Bank of New Zealand*. He was of opinion Dr. Morrison's three attendances in Dublin were unreasonable, and that only one should be allowed. They were unable to see any exceptional circumstances in the case that would justify the Taxing Master in allowing more than one guinea a day to the Dublin doctors. The Taxing Master was bound by the schedule, even in the case of doctors of exceptional eminence, and, Mr. Justice Barton and Mr. Justice Wright concurring, the fees were reduced to the schedule allowance. From this decision the plaintiff appealed.

When the appeal was heard last week, evidence was adduced proving that the award of fees to the medical witnesses by the Taxing Master was reasonable considering the amount of time and the eminence of some of the surgeons, and that they were entitled to the increased allowance which was under dispute.

Lord Justice Fitzgibbon, in delivering his judgment, considered whether this was an exceptional case, and what were the special grounds. He was of opinion that the questions put to the Taxing Master and the answers given did not in any way justify them in making this an exceptional case so as to increase the allowance under the scale. This was an allowance "per day" for attendance at the trial. It was almost impossible to lay down a hard and fast rule as to what was an exceptional case, but he was clearly of opinion that there were no exceptional circumstances in this case, and that the Taxing Master should not have exceeded the scale in his allowances.

Lord Justice Walker and Lord Justice Holmes concurred, and the appeal was accordingly dismissed.

Obituary.

DR. R. L. M'INTIRE, OF KILLINEY.

We regret to have to record the death of Richard Litton M'Intire, M.D., who has in his later years lived in retirement in Killiney, and who had reached the advanced age of eighty-six. He graduated in Arts in Dublin University in 1836, having obtained honours in his undergraduate course, and in Medicine in 1843. He was one of the oldest of the existing Fellows of the Royal College of Surgeons of Ireland, having obtained his Fellowship in 1845. Five names only had remained on the roll before his in seniority at the date of his death. He was educated at the Richmond and Whitworth Hospitals at a time when they had reached a commanding position under the professional guidance of Doctor (afterwards Sir Dominic) Corrigan, Richard Carmichael, Edward Hutton, Robert Adams, J. M'Donald, and Samuel Litton. Among his student colleagues and intimate friends were Benjamin E. MacDowel, Samuel Gordon, Frederick Kirkpatrick,

William A. Elliott, and Humphrey Minchin, names still familiar as men who attained a front rank in the practice of their profession. Dr. M'Intire settled in Coleraine, where he practised until the year 1891, when he retired, having gained a large practice and high provincial fame, and where his name is still remembered with feelings of warm regard.

ROBERT CROMIE, C.M., J.P., CLOUGH.

It is with sincere regret we notice the death of Dr. Robert Cromie, of Clough. He was one of the oldest members of the medical profession in Ireland. Three score years and seven have passed since he took his C.M. in Glasgow, and soon afterwards settled in Clough, a quiet little village near Downpatrick, in the midst of a prosperous settlement of Presbyterian farmers.

His sound knowledge of his profession, his conscientious fulfilment of its duties, and his trustworthy nature, endeared him to the undemonstrative northerners to whom in his district he became not alone their physician, but their friend, and three generations looked to him as adviser and sought his sympathy in all their trials.

Like Balsac's "Village Doctor," his ambition was the welfare of his people and the faithful discharge of the high and holy duties of his profession. He had become to them as a guide and trusted counsellor in all the affairs of life. He was one of them; his loves and likes and hates were theirs, and now he sleeps with the grand-sires of his patients, those who had known him when he returned in 1834 just qualified from Scotland. From our first number to the present, he subscribed to *THE MEDICAL PRESS AND CIRCULAR*, and found in the fearless advocacy of medical rights by Dr. Arthur Jacob and his no less gifted son, Dr. A. H. Jacob, a pleasing evidence that a father and son were found who could and did pursue truth for its own sake, regardless of all else.

When the Lord Chancellor conferred a J.P. on Dr. Cromie, his loyal clients looked on the honour as a natural recognition of his worth, and on his acceptance of it as the civility of a loyal subject conforming to the Royal pleasure.

His death is mourned from Belfast to Kerry, and from Downpatrick to the sea on both sides of Strandforalough, and with the biblical phraseology which is so familiar in the north, the mourning thousands in Clough summed up his righteous, active life in the words, "He rests from his labours, and his works do follow him."

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

DIPHTHERIA.

To the Editor of *THE MEDICAL PRESS AND CIRCULAR*.

SIR,—The interesting and informing communication of Dr. Frederick Palmer in your last week's issue calls for one or two remarks. He quotes the opinion, from a work on "Diseases of the Nose and Throat," the first edition of which was published in 1894, that "extension of the exudation to the soft palate and uvula is pathognomonic of diphtheria as contrasted with follicular (lacunar) tonsillitis." The point is rightly made one of considerable significance, and on reference to the second edition of my systematic work, published seven years previously, will be found the following words:—"In many of these cases use of the rhinal mirror will reveal patches on the posterior surface of the soft palate and uvula. The fact of an exudation on the uvula, and especially on its posterior surface, is regarded by me as a point of almost pathognomonic importance." (a)

I am not aware, although I am open to correction, that this point had been noted by previous writers on the subject. It is not mentioned in Morell Mackenzie's classical essay, but it is elaborated in my own monograph (b) wherein there are given four examples, each

(a) "The Throat and its Diseases," 2nd edition, 1897, p. 329.

(b) "Diphtheria and its Associates," 1st edition, 1895, p. 67

of which is illustrated by a coloured drawing of the faucial appearances.

With regard to nasal diphtheria it is true that many cases of fibrinous rhinitis which used not to be considered diphtherial have been found to be so on bacteriological examination, and also that the majority of cases in which membrane is confined to the nares run a benign course, and with but few evidences of systemic infection. This, I suggest, is due to the bactericidal properties of the nasal secretions.

But statistics do not justify the assertion that nasal diphtheria only "sometimes, though not often, presents malignant characteristics." An analysis (a) of a thousand consecutive cases showing the relative frequency of sites attacked, which occurred at the North-Western Fever Hospital, proved that while the nostrils alone were attacked but in two cases, diphtheria was manifested in the nostrils associated with either fauces or fauces and larynx in 211; and that as to mortality, one of the two cases in the first class was fatal and 157 of the second. In fact, that the mortality is highest where the nares are involved in association with either fauces or larynx, or with both.

May I plead once more for the use of the adjective "diphtherial" instead of "diphtheritic," the latter being, to say the least, redundant, since Bretonneau and Trousseau changed the word of the disease from *diphtheritis* to *diphthérie*—otherwise *diphtheritis* to *diphtheria*—on the ground that the *itis* was not justified by the moderate amount of pyrexia which characterises the disease?

I am, Sir, yours truly,

LENNOX BROWNE.

Manafield Street, London, W.

Jan. 20th.

SUPERFETATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the last issue of your journal you publish a most interesting communication by Dr. Charles O'Gorman on "Some Abnormalities in a Midwifery Practice." His reminiscences are all personal, and are well worthy of attention. It is a pity, however, that he has not treated some of his cases with more detail, and especially that case which is so briefly referred to in his concluding paragraph, and of which he says, "This case proves that it is possible for superfetation to occur at (sic) a far advanced existing pregnancy." Now, Sir, this is a remarkable statement, and one to the elucidation of which Dr. O'Gorman might well have devoted more space—perhaps, indeed, more space than even your hospitable columns could afford him. I think that I am correct in stating that with one accord such works on midwifery as allude to the condition of superfetation say that its occurrence is impossible. In this connection it must be borne in mind that there are two somewhat similar-sounding but widely different terms. The term superfecundation is used to imply the fertilisation of two ova, which have been set free at the same ovulation, by different but closely following sexual acts. The term superfetation, on the other hand, implies the impregnation of two ova which have been set free at different ovulations, and which therefore can only be fertilised by widely separated sexual acts. One condition is a possibility, and has been proved by such occurrences as the delivery at one birth by a negress of a black and a white infant of the same age. The other condition is an impossibility, inasmuch as ovulate the ovum never so much, there is no *modus eundi*—if I may use the term—between the ovum and the spermatozoon. Would it not be more legitimate to suppose that in Dr. O'Gorman's undoubtedly curious case the condition of the female triplet was due to the unfair alliance which existed between the two male infants, who had a common placenta—that it was, in fact, a case of the weaker having gone to the wall, or, as some of our friends would put it, that it was another injustice to woman? In the hope that Dr. O'Gorman will amplify his account,

I am, Sir, yours truly,

X.

(a) *Op. cit.*, p. 146.

DOUBTFUL CASES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I feel very grateful to the Statistical Committee of the Metropolitan Asylums Board for having placed us in possession of the returns available to date of the present epidemic of small-pox in the Metropolis. There is one feature in their report, however, which leaves me perplexed, viz., the extraordinarily heavy mortality among the so-called "doubtful" cases. Candidly, I view these doubtful cases with suspicion and my object in writing, is to beseech the Board to take an early opportunity of reassuring us in reference thereto. Would it not be possible to ascertain in many of these doubtful cases what ground there was for the patients' statement that they had been vaccinated. Would it not be well also to state whether the non-discovery of vaccination marks was due to the presence of the rash on the usual site of the scars? Lastly, one would like some explanation of the anomalous and, to me, inexplicable circumstance, that the mortality in doubtful cases is so much higher than in persons admitted non-vaccinated.

The proportion of doubtful cases is so large as to vitiate any conclusions based on the separation of the patients into vaccinated and non-vaccinated, and the moral effect of the recently published statistics is thereby greatly impaired.

Practitioners must be prepared to face these difficulties if they are to command the confidence of their section of the public, and we look to the medical officers of the Metropolitan Asylums Board, or failing them, of the medical experts attached to the Local Government Board, to assist us at this juncture.

I am, Sir, yours truly,

PRACTITIONER.

Liverpool Medical Institution.

At the annual meeting of this institution, held on January 9th, the following office-bearers, members of Council, and committees were elected:—President, Mr. Rushton Parker. Vice-Presidents, Dr. Edward Adam, Dr. J. M. Hunt, Dr. John E. Gemmell, and Dr. Permewan. Honorary Treasurer, Dr. Briggs. Hon. General Secretary, Dr. J. R. Logan. Hon. Secretary to Ordinary Meetings, Dr. J. Hill Abram. Hon. Librarian, Dr. Leslie Roberts. Council: Dr. James Barr, Dr. R. J. M. Buchanan, Mr. G. A. Hawkins-Ambler, Dr. W. Macvie, Dr. E. Nicholson, Dr. J. Lloyd Roberts, Mr. Edgar Browne, Dr. W. M. Cairns, Mr. D. Douglas-Crawford, Dr. Ernest Nevins, Prof. Sherrington, and Dr. Warrington. Pathological and Microscopical Committee: Prof. Boyce, Mr. R. A. Bickersteth, Dr. R. J. M. Buchanan, Mr. D. Douglas-Crawford, Dr. John Hay, Dr. Macalister, Mr. Monsarrat, Mr. Newbolt, Prof. Sherrington, and Dr. Warrington. Journal Committee: The Hon. Sec. to Ordinary Meetings, the Hon. Sec. Pathological Section, Dr. Barendt, Mr. F. C. Larkin, Mr. Newbolt, Prof. Paterson, Mr. W. Thelwall Thomas, Dr. Arthur J. Wallace, Dr. Permewan. Auditors: Dr. J. Lloyd Roberts and Dr. Dawson.

A Neurasthenic Bankruptcy.

In the examination of a bankrupt at Oldham, a few days since, attention was called to the fact that there were no less than eight doctors among the claimants. The debtor explained this plethora of medical claims on the ground that no treatment had been successful. As the assets only amounted to some £10, the dividend is likely to be small. Moral, do not give credit to neurasthenic patients.

The Skull of Sir Thomas Browne.

DR. OSLEE, the well-known Professor of Medicine at the Johns Hopkins University, Baltimore, has presented a casket to the Norfolk and Norwich Hospital to form a receptacle for the skull of Sir Thomas Browne, the author of "Religio Medici." The headless body of the famous Norwich physician lies in the church of St. Peter Mancroft, the authorities of which have frequently endeavoured to get back the skull from the hospital. The casket is of crystal glass with silver-gilt mountings, and is set on a stand of ebony. Quotations from the "Religio Medici" are displayed on gilt plates.

There is something of irony in the quotation: "I believe that our estranged and divided ashes shall unite again; that our separated dust after so many pilgrimages . . . shall . . . again . . . make up their primary and predestinate forms." Certain antiquaries are unkind enough to express doubts whether the skull in question is really that of Sir Thomas Browne.

West London Medico-Chirurgical Society.

THERE will be a "Discussion on the Treatment of Inoperable Cancer" at the next meeting of above society on February 9th, 8.30 p.m., at the West London Hospital. Mr. Alfred Cooper, Mr. Stanley Boyd, Mr. Butlin, and Mr. Henry Morris will speak. The annual dinner is on Wednesday, February 19th, 7.30 p.m., at Frascati's Restaurant.

A Victim to Duty.

AN inquest was held last week on the body of Dr David Ramsay, of Raunds, Northampton, who died of blood-poisoning due to accidental inoculation during an operation. It appears that while opening an abscess of the foot the knife slipped, and the point entered deeply into the middle joint of the left index finger. The external wound was trivial, but suppuration set in on the following day, and he ultimately succumbed to exhaustion.

The Sanitary Institute.

WE are asked to announce that a Congress of the Sanitary Institute will be held at Manchester on September 9th-13th. Section I.—Sanitary Science and Preventive Medicine—will be presided over by Sir J. Crichton Browne, M.D., LL.D., F.R.S., F.R.S.E. Section II.—Engineering and Architecture—will be presided over by Sir Alexander Binnie, M.Inst.C.E. Section III.—Physics, Chemistry, and Biology—will be presided over by Professor A. Sheridan Delépine, M.B., C.M., B.Sc. Eight technical conferences will also be held in connection with the Congress. The Institute announces that a donation of one hundred guineas has been made by the Vinolia Company to the fund for the new building and endowment of the Parkes Museum.

Nursing of the Sick Poor in Workhouses.

THE President of the Local Government Board has appointed from among the officers of the Department a Committee on this subject, consisting of Mr. Grant Lawson, M.P., Parliamentary Secretary; Mr. W. E. Knollys, C.B., Chief General Inspector and one of the Assistant Secretaries; and Dr. A. H. Downes and Dr. A. Fuller, Poor-law Medical Inspectors, with Mr. R. H. A. G. Duff as Secretary. The Committee will inquire and report as to the qualification of nurses and probationers, the difficulties in obtaining an adequate supply of these officers, and the regulations necessary to define the respective duties of the master or matron and of the superintendent nurse.

Royal College of Surgeons of England.

THE following are the lecture arrangements at the College for February and March. Each lecture will be delivered at 5 o'clock p.m. precisely:—Mr. Charles Powell White, F.R.C.S. (Erasmus Wilson Lecturer), will lecture on "The General Pathology of Tumours," on Monday, February 10th, Wednesday 12th, and Friday 14th. Dr. T. G. Brodie (Arris and Gale Lecturer), on "The Pulmonary Circulation, more particularly in relationship to variations in Cardiac Activity," on Monday, February 17th, Wednesday 19th, and Friday 21st. Prof. W. McAdam Eccles, on "The Imperfectly Descended Testis: its Anatomy, Physiology, and Pathology," on Monday, February 24th, Wednesday 26th, and Friday 28th. Prof. F. G. Parsons will lecture on "The Blood-Vessels of Mammals in relation to those of Man," on Monday, March 3rd, Wednesday 5th, and Friday 7th; and on Monday 10th Prof. C. Stewart, LL.D., F.R.S., will commence a course of six lectures on "The Organs of Respiration," these latter being continued on each succeeding Wednesday, Friday, and Monday until March 21st.

Notification.

DR. JOHN DUNNE, of Southampton Street, Camberwell, was summoned last week for neglecting to notify a case of diphtheria. It was stated in evidence that the certificate had been duly made out and posted, and

the magistrate dismissed the summons, with two guineas costs against the Camberwell Borough Council.

Compulsory Vaccination in America.

THE law has a strong arm in the United States. It is reported that a mild sort of riot was caused in Minneapolis on Saturday by the forcible vaccination of three hundred persons. The city has an ordinance making it illegal for anybody to be unvaccinated, and on Saturday advantage was taken of the presence in the Chamber of Commerce building of a number of persons who were conscientious objectors, and who had defied the law, to vaccinate them by force. A corps of physicians was sent for, and with the assistance of a strong force of police the work of vaccination was begun. The friends of those who were inside the building heard of what was going on, and tried to storm the structure to effect their release. The police reserves had to be called out, and a cordon was formed round the Chamber of Commerce, after which the doctors continued their work uninterrupted. Among the persons thus forcibly vaccinated were a number of wealthy residents, and at least two persons who are millionaires.

The Lady Doctor Difficulty.

FIVE of the governors of the Maccolesfield Infirmary have given notice of their intention to retire in consequence of the action taken by the majority in the dismissal of Miss Murdoch Clark in deference to the protest of the honorary male medical staff against her appointment as lady doctor to the infirmary.

Government Vaccine Lymph.

NOTICE is given by the Local Government Board that the supply of glycerinated lymph is limited, and will in future be supplied in preference to public vaccinators in districts where small-pox prevails. It is pointed out that this lymph is intended more particularly to be used for primary vaccinations, and it is added that the Board is prepared to sanction expenditure by Boards of Guardians on lymph from other than Government sources. In a notice to the public the Board advise that medical advice should be promptly obtained in all cases of supposed chicken-pox, and that persons who come into contact with such cases should take the precaution of being vaccinated. It is also advised that unvaccinated persons should subject themselves to inspection within a few days of the operation in order to establish its success or otherwise.

Re-vaccination at Windsor.

SPECIAL precautions are being taken at Windsor Castle against small-pox. All the Royal servants, police, and employees at the Castle and on the Royal demesne have been vaccinated, and now an order has been issued for all tradesmen and their assistants serving the Castle to undergo the operation.

Pharmaceutical Society of London.

THE following have passed Preliminary Examination:—R. H. Orr, R. E. Campbell, J. Marron, T. H. H. Bennett, C. Carmichael, W. E. W. Harpur, A. McCombe, R. Courtney, W. P. Doohan, T. H. Brabazon, A. M. Gamble. Ten candidates were rejected.

The following passed Pharmaceutical License Examination:—F. C. Large, W. F. Cuttifford, F. B. Anglely, W. M. Kennedy, G. G. Wilkinson. Twelve candidates were rejected.

Society of Apothecaries of London.

THE following passed the January examinations:—Surgery.—J. W. W. Adamson (Section II.), A. G. H. Anthonisz (Section II.), A. H. Bell, H. E. Darlington, A. Dewar, F. M. Payne (Section II.).

Medicine.—J. W. W. Adamson (Section II.), A. A. E. Baptist, F. G. Bennett (Section I.), E. C. Curtis, C. J. Francis, J. Hunter (Sections I and II.), W. Miles, R. Rees (Sections I and II.), H. Salomon.

Forensic Medicine.—J. Hunter, T. G. Miles, R. Rees, G. Roper, H. Salomon.

Midwifery.—J. J. Anning, F. G. H. Cooke, F. I. M. Jupe, F. H. Maberly, E. J. Miller.

The qualifying diploma of L.S.A. in medicine, surgery and midwifery was granted to the following candidates: J. W. W. Adamson, A. G. H. Anthonisz, A. A. E. Baptist, A. Dewar, C. J. Francis, F. M. Payne, and R. Rees.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

DR. ADAMS.—Our correspondent is to be commended for the wisdom of his decision. Probably nothing more will be heard of the matter. Should, however, unhappily, any further steps be taken, it would be expedient to consult the Medical Defence Union.

HOT-WATER BOTTLE SUBSTITUTE.

A SIMPLE plan suggested by a writer in the *Philadelphia Medical Journal* is to wrap an ordinary electric light bulb in flannel and apply to the part. The lamp is attached to an ordinary flexible connection, and when the current is turned on it gives off a steady heat very comforting in painful affections of the chest abdomen, &c. As long as the lamp is alight the heat is maintained, and does not decrease, as with a hot-water bottle.

QUERRENS (Bolton).—The symptoms you describe are suggestive of gall-stone. The jaundice may be so slight and fleeting as to escape the attention both of patient and of medical attendant. It is perfectly true that in some cases nature effects a cure by establishing external or internal biliary fistulae. At the same time, the risks of peritonitis and other grave complications are so great that in well marked cases delay is unjustifiable. In these days of advanced abdominal surgery we would advise immediate operation in your patient's case—"the sooner the better." Olive oil is probably the best alternative treatment; both salicylate of soda and turpentine have proved useless.

"CONGENITAL DISPLACEMENT OF HIPS."

IN our issue for Jan. 15th we published a paper by Mr. E. Noble-Smith. It should have been stated that the paper, as printed, was an abstract of one read before a meeting of the British Orthopaedic Society, held at the National Orthopaedic Hospital, on Saturday, Dec. 14th.

DR. H. D. POPE.—Your letter is unfortunately crowded out at press. We hope to have space for it in our next.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, JAN. 22nd.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m. Dr. Arnold Chaplin: The Treatment of Pleuritic Effusion.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover Square, W.).—5 p.m.

FRIDAY, JAN. 24th.

EPIDEMIOLOGICAL SOCIETY (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Discussion on Dysentery in Asylums, to be opened by Dr. W. F. Mott. Discussion on the Relation of the Dysentery of Asylums to that of South Africa, to be opened by Dr. J. W. Washbourn.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases, followed by discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

MONDAY, JAN. 27th.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (20, Hanover Square, W.).—8 p.m. Communications by—Mr. Ernest B. Dowsett: Sections of a Human Tooth, showing Plicid-Dentine (?); Mr. C. W. Glasgerton: A Composite Odontome; Mr. F. W. Collingwood: A Slight Modification of Patterson's Prolongation Apparatus; Mr. E. Lloyd-Williams: A Fatal Case of Alveolar Abscess; Dr. E. A. Peters: Suprarenal Extract in Dental Surgery.

DUBLIN.

THURSDAY, JAN. 23rd.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION (Trinity College).—8.15 pm.

FRIDAY, JAN. 24th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Medicine, College of Physicians, 8.30 p.m.

MONDAY, JAN. 27th.

DUBLIN UNIVERSITY.—Final Medical Examinations. Sections B and Medicine. M.B. Degree.

Appointments.

BREDDARD, A. P., M.D., M.B.C.P., Physician to the West London Hospital.
BROWNLOW, HARRY LUGAN, F.R.C.S. Eng., L.R.C.P. Lond., Honorary Assistant Surgeon to the Royal United Hospital, Bath.
BRYAN, H. J., M.B.C.S., L.R.C.P. Lond., District Poor-law Medical Officer for Chatham.
CANT, A., M.B., B.Ch. Birm., M.B.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory Acts for the Colleshill District of the County of Warwick.
COOKE, WILLIAM H., F.R.C.S. E., L.R.C.P., Assistant Surgeon to the Royal United Hospital, Bath.
FLINT, T. B., M.B.C.S. Eng., L.R.C.P. Lond., Honorary Medical Officer to the Devonshire Hospital, Buxton.
HEWER, OSCAR M., F.R.C.S. Eng., Certifying Surgeon under the Factory Acts for the Thorpeley Urban District of Cheshire.
LACE, FREDERICK, F.R.C.S., Surgeon to the Royal United Hospital, Bath.

PERRY, S. H., M.B.C.S., L.R.C.P., Medical Officer of Health under the Rural District Council of Spalding.
PETTYBRIDGE, W. L., M.D., B.Sc. Lond., M.B.C.S., L.R.C.P., Honorary Anaesthetist to the Royal Eye Infirmary, Plymouth.
RAY, JOHN HOWSON, Ch. M. Vict., F.R.C.S., Surgeon to the Manchester Children's Hospital, vice Mr. G. A. Wright, F.R.C.S.
REYNOLDS, F. E., M.B.C.S., Temporary Medical Officer for the Stoke Gabriel District by the Totnes Board of Guardians.
TERRY, GEORGE HENRY, F.R.C.S. Edin., M.B.C.S., L.S.A., Honorary Surgeon to the Royal United Hospital, Bath.
THOMPSON, W. H., M.D. E.U.I., King's Professor of the Institute of Medicine in the School of Physic, Trinity College, Dublin.
TWORT, F. W., M.B.C.S., L.R.C.P. Lond., Assistant Bacteriologist to the London Hospital and Medical College.

Vacancies.

Brecon Infirmary.—Resident House Surgeon. Salary £100 per annum, with furnished apartments, board, attendance fire, and gas. Applications to W. Powell Price, Secretary, 6, Bulwark, Brecon, South Wales.
City (Fever) Hospital, Aberdeen.—Resident Physician. Salary £100, with board and rooms. Apply before Jan. 22nd, stating age and qualifications, to Medical Officer of Health, City Buildings, Aberdeen, from whom information as to duties can be obtained.
County Asylum, Rainhill, near Liverpool.—Assistant Medical Officer. Salary commences at £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent as soon as possible.
Hospital Vessel stationed with North Sea Fishing Fleets.—Young Medical Man wanted at once as Surgeon and assist in religious work. Salary £3 3s. all found. Apply, Royal National Mission to Deep Sea Fishermen, 181, Queen Victoria Street, E.C.
London Hospital, Whitechapel, E.—Assistant Director of the Pathological Institute at this Hospital. Salary £200 per annum. Applications to G. Q. Roberts, House Governor.
Metropolitan Asylums Board.—Assistant Medical Officer to the Fever and Small-pox Hospitals. Salary commencing at £100, with board, lodging, attendance, and washing. Immediate applications. (See advt.)
New Zealand Government, Thermal Springs.—Bacteriologist required. Apply to the Agent-General for New Zealand, 13, Victoria Street, London, S.W.
Salford Union.—Assistant Resident Medical Officer. Salary £150, per annum, with furnished apartments and attendance (but not rations) in the Infirmary. Applications immediately to F. Townson, Clerk to the Guardians, Union Offices, Eccles New Road, Salford.
Scalebar Park, Burley-in-Wharfedale.—Medical Superintendent. Salary £500 per year, with furnished house, board and attendance. Applications to Messrs. Dixon and Morne, Asylums Department, County Hall, Wakefield.
The Royal Infirmary of Edinburgh.—Pathologist. Salary £400 per annum. Applications immediately to William S. Caw, Treasurer and Clerk.
West Herts Infirmary, Hemel Hempstead.—House Surgeon. Salary £100 per annum, with furnished rooms, board, fire, light, washing, and attendance. Applications immediately to the Hon. Secretary at the Infirmary.
Whitechapel.—Eastern Dispensary, Leman Street.—Resident Medical Officer. Salary £140 per annum, with furnished residence, coals, and attendance. Applications immediately to George W. Hiley, 60, Great Prescott Street E. (See advt.)
Wrexham Infirmary.—House Surgeon. Salary £100 per annum, with board, washing, &c. Applications to S. D. Edisbury, Secretary.

Births.

GOURLAY.—On Jan. 17th, at Lidlall House, Shifnal, Salop, the wife of F. Thornbrough Gourlay, M.B., of a daughter.

Marriages.

KING-COOKE.—On Jan. 15th, at St. Mary's Church, Par, Cornwall, Charles Kirwan King, M.A., Exeter Coll., Oxford, only son of Dr. T. W. King, of Dorking, Surrey, to C. Louise, youngest daughter of the late Rev. G. Cooke and Mrs. Cooke, St. Mary's, Par.
MACPHERSON-BENT.—On Jan. 16th, at St. Mary's Church, Balham, Captain John Duncan Graham Macpherson, B.A.M.C., eldest son of Lieut.-Colonel Macpherson, Southsea, to Hilda Frances Estelle, younger daughter of the late Dr. Bent and Mrs. Bent, Balham.
STOTT-JACKSON.—On Jan. 14th, at All Saints' Church, Hollingbourne, William Gordon Stott, Staff Surgeon R.N., to Clarissa Jackson, Hollingbourne, Kent, widow of the late Henry S. Jackson, Staff Surgeon R.N., eldest daughter of George Murray, Esq., Montreal.

Deaths.

FORSAITH.—On Jan. 18th, at Shandon, New Eltham, Kent, Elizabeth, widow of the late Henry Spencer Forsyth, of The Vale, Ramsgate, and elder daughter of the late Robert Rowley, M.D., of Regent's Park, London.
HILLS.—On Jan. 18th, at The Chantry, Norwich, suddenly, of heart failure, William Charles Hills, M.D., aged 73.
JEFFCOAT.—On Dec. 20th, 1901, at Telskop, O.R.C. (killed in action), Captain H. J. P. Jeffcoat, Royal Artillery, D.S.O., third son of Dep.-Sur.-Gen. J. H. Jeffcoat, of 12, Avenue Elmers, Surbiton, in his 30th year.
MACRAY.—On Jan. 14th, at Huelva, Spain, Mary Bannerman (Molly), daughter of William Alexander Macray, M.D., aged 13 years.
NADE.—On Jan. 19th, at the residence of Surg.-General Meane, 98, Ebury Street, S.W., Surg.-General W. Nash, B.A.M.C., of pneumonia, aged 62 years.

Vienna Clinical Lectures.

MYIASIS INTESTINALIS.

By PROF. SCHLESINGER, M.D.,
Of Vienna.

[FROM OUR VIENNA CORRESPONDENT.]

I AM enabled to show a specimen of a case of myiasis in an engineer, æt. 23, who had suffered for a year and a half with indefinite pain in the bowels, dysentery, fever, emaciation, and death. The early history was more like chronic disturbance of the bowel, but six months after the onset he presented persistent dysentery with a very offensive smell, but no fever or tenesmus at this time. This lasted about six weeks; then came a three months' pause. The stools during this interval contained blood, pus and mucus. About the end of May, 1901, large quantities of insects like maggots came away from the bowel at three different times. Again the stools became normal. In June diarrhoea recommenced, but from what cause it is difficult to say.

About the end of that month fever, emaciation set in with a repetition in the stools of blood and matter closely followed by large quantities of insects and ova.

At this period a new phase commenced, marked by symptoms of obstruction, which became very prominent, but no insects were observed. Constant anorexia, frequent pulse, without any actual vomiting, were the principal symptoms later on suggesting multiple lesions in the bowel. No albumin was found in the urine, although casts were present for four weeks.

No amœba, entozoon, or tuberculous bacilli were to be found in the stools.

It may be noted here that a tumour in the sigmoid flexure was observed as early as 1900. In May, 1901, it was again observed with a soft boggy swelling in the right ileo-sacral fossa. The patient retained consciousness throughout till he died in October from inanition.

The diagnosis of myiasis gastro-intestinalis is not easy to determine, as the larvæ may settle anywhere in the alimentary tract giving rise to indefinite symptoms in the stomach and intestine. The presence of other parasites such as *ankylostomum* *ascarides* may be difficult to distinguish, and the same remark applies to other morbid changes in the canal, such as enteritis pseudomembranæ, enteritis follicularis, and other dysenteric conditions. I think that all dysenteric conditions having no clear cause of origin should be closely examined for myiasis. The absence of any larvæ in the stools is no proof of their absence, because weeks or months often pass before anything of this nature can be detected, and the symptoms may remit for long periods; this should be noted as a conclusive symptom of myiasis. The dipteroid larvæ are usually thrown off at an early stage, while

the pupæ are very rarely so. The diptera of the insects is the only suitable species for producing myiasis, as the larvæ are contained within the abdomen, although it is not unreasonable to suppose that multiplication goes on within the human canal. There is one noteworthy fact that pedogenesis goes on rapidly, which is probably due to the altered habitat of the larvæ.

In the prophylaxis of these cases raw flesh should be carefully avoided, being one of the principal aliments of these parasites. The therapeutic treatment is much the same as for other local parasites in the bowel, and has to be repeated frequently before the parasite is dislodged.

Following on the above, Weichselbaum showed a preparation of the morbid conditions present in this case. He reported that the whole body was emaciated except the kidneys, which had undergone fatty degeneration; the large intestine showed no signs of change. Both sides of the colon contained fæces; no tubercle and no peritonitis was present. The bowel was distended above the cæcal valve, while in the transverse and descending colon a firm resisting tumour was present. After removing the fæces a hundred small ulcers were found along the surface of the mucous membrane of the bowel, particularly in the region of the ileo-cæcal valve, flexura hepatica, and colon descendens. The margins of the ulcers were undermined, and the submucous tissue was raised about five millimetres. The ulcers were ten to fifteen centimetres in diameter, and extended round the whole circumference of the bowel. In the cavity of the ulcer a trabeculæ of muscular fibre and submucosa was usually present. The microscope showed that the muscular tissue was deeply involved, while the subserous membrane was greatly thickened. The surface of the ulcer had a necrotic sheath of small infiltration cells, but no larvæ of insects could be discovered. The immediate cause of death was inanition and obstruction of the bowel.

The character of the ulcer and the duration of the disease excluded dysentery, tubercle, and syphilis. The smallness of the ulcers in the bowel tended to point to some irritating agent in the canal.

From the clinical history we must assume that the patient at some anterior date swallowed a fly, larva, or ova of some insect whose germination would be suitably propagated in the human intestinal canal. If we assume a fly, the diptera is the only probable one suited for this sort of genesis, as the ova are usually emitted from the body in a larval state ready to subsist in the alimentary canal, as it can easily at this stage penetrate the submucous membrane and protect itself behind the mucus. This accounts for the hæmorrhagic stools, bacteria, and necrotic *débris*. The growth of the ulcer may be accounted for by the prolonged sojourn of the larvæ at these points. It becomes a more difficult matter to explain how large quantities of larvæ would come away with one or two stools, after which none would

be seen for a long time, even for weeks. It is just possible that idiosyncrasy has much to do with this, that it was a fresh attack, or maybe, a new brood was about to be formed, and the old having matured commenced its migration to give place to a new generation. This theory seems the most logical when we consider that each grub would occupy one to two millimetres, and that four stools brought away large masses of these larvæ, while the ulcers are shown post-mortem to be distributed over the bowel and not located at any one point of the canal. Possibly the mature brood was thrown off for the young to increase by pædogenesis, and be discharged in the same fashion when mature. Against this theory is the fact advanced by entomologists, who tell us that the larvæ of the diptera have never been observed to assume this character. Circumstances may alter the conditions.

In the post-mortem we have seen ulcers apparently gradually becoming wider till a few of them have fused into one large necrotic lesion, while the large burrows underneath the mucous membrane proves that a large group were present at one time.

Myiasis intestinalis presents specific morbid changes, are distinct in the necrotic submucosa, subsequently forming ulcers. In this respect it somewhat resembles the amœba of dysentery. Another similar change is related by Solowief in "*Balantidium Coli*." In suppurative folliculitis you have ulceration, but shorter in duration, while extending along the bowel but confining itself to the follicle. As to the frequency of this disease it would be dangerous to conjecture, but from the cases reported they must be more frequent than is generally supposed.

A METHOD OF TREATING CERTAIN CONDITIONS OF JOINTS. (a)

By R. L. SWAN, F.R.C.S.,
Surgeon to Stevens' Hospital.

It is true that it has long been the practice of surgeons to lay open joints in a septic condition and treat them with antiseptics. Pure carbolic acid has been used, but many surgeons fear the risks of its application to the tissues. That this risk is not a light one has been well proved. I remember a case under the care of a late eminent surgeon of this city in which the application of equal parts of the lin. iodi and pure carbolic acid to an unbroken skin surface was followed by symptoms of carbolic acid poisoning and a fatal result.

Phelps, an American surgeon, has recently tried to reintroduce the practice. After a wide opening into the abscess cavity or the joint, the part is cleansed by curettement. The cavity is then filled by pure carbolic acid, which is allowed to remain for one or two minutes. It is then thoroughly washed out by alcohol. Into the wound so prepared a thick glass drain is inserted and tamponaded. *Morbus coxæ* was the disease for which this treatment, for which great success has been claimed, was first proposed. The fact that so large a cavity can be treated with pure carbolic acid deserves consideration.

The same treatment has been extensively adopted at the Tübingen Klinik by von Bruns, with some modifications. Those cases were obviously mixed infections, and demonstrated very plainly that with certain precautions pure carbolic acid could be used as an application to extensive surfaces without risk. It is unnecessary to discuss the reasons of this safety.

(a) Read before the Surgical Section, Royal Academy of Medicine in Ireland, Jan. 17th, 1901.

They will probably be evolved from the details of the practice which I venture to bring under the notice of the Academy. It is a means of dealing with certain conditions of joints which, if treated by ordinary and well-known methods, show a tendency either to progress to the destruction of the joints, dissemination of the diathetic elements, or in other instances to manifest an indeterminate series of recoveries or recurrences, which, by interfering with the functions of an important joint, destroys, or renders difficult, the lifework of the person affected.

The study of primary tuberculous disease of the synovial membrane accompanied by hydrops articulari first led me to the consideration of the following questions:—Why, when we have all witnessed the decided recoveries after operative interference in tuberculous disease of the peritoneum, should we hesitate to deal in a similar manner with the synovial membrane of a joint? Are we not in a better position to deal with a joint cavity than with the peritoneum? In the one we can immobilise or move the articulation at will; we can also proceed in a far more radical and complete manner than with the peritoneum, enclosing as it does organs of vital moment, and in its vast extent forming recesses which it is difficult to imagine can be directly approached. Six years ago, in 1895, a girl, æt. 7, showed the following condition. The right knee-joint was distended and flexed at the usual angle in such cases. There was fluctuation, although pain was not complained of. She walked lame from mechanical reasons. The swelling had developed gradually in a period of ten weeks. There was no perceptible heat. No involvement of the osseous structures contiguous to the joint could, by the most careful examination and comparison, be discerned. The family history disclosed tuberculosis in near relatives. In my belief this seemed to be a typical case of primary tuberculous disease of the synovial membrane. I confess the routine treatment for such a case had always seemed to me to be thoroughly unsatisfactory, and to witness patient after patient going from bad to worse, under the means usually adopted made one feel humiliated. I refer to immobilisation, the application of resolvers, such as Scott's dressing or iodine, Bier's treatment, blistering, aspiration, the injection of agents to cause destruction or encapsulation of the bacilli, such as chloride of zinc or iodoform. I had tried them *ad nauseam*. I had seen, no doubt, an improvement in a few of those cases, and a partial recovery in very few, but the majority travelled by the familiar road which led to the involvement of the capsule and the surrounding parts in a gelatinous degeneration—loss of joint, or limb, or life, the result.

In the case above referred to I opened the joint by cutting across the patella, making first a flap on the skin convex upwards. The patella was easily cut through with a sharp knife and the interior of the joint displayed. It was filled with a pale, whey-like fluid containing shreds of flocculent fibrin. The synovial membrane was congested at its reflection off the cartilage, and the fringes were oedematous. I irrigated the joint for a considerable time with saline solution, and removed every loose particle of flocculent material. Having dried the surfaces, I applied pure carbolic acid with a stick to the synovial membrane, and again irrigated freely with sterilised water. I then closed the joint. Suturing the patella with catgut and the skin with silk worm gut, leaving no drain. A plaster of Paris bandage was applied over the dressings.

No trouble was ever afterwards experienced. I saw the girl at Howth, last year, where she had come from the country with her friends. It was five years after the operation. It would be impossible,

except for the cicatrix, to tell which knee had been the diseased one.

In thirteen cases of a similar kind in which I subsequently adopted such a course, I modified the proceeding, not thinking it necessary to divide the patella. Good access to the joint may be obtained by making an incision, convex backwards, reaching from the lower part of the inner edge of the ligamentum patellæ to a point in the adult about two inches above the base of the patella. All bleeding having been arrested the joint is laid open. In closing the wound three layers require adaptation and suturing:—1. The synovial membrane. 2. A layer aponeurotic below and aponeurotic and muscular above; and 3, the skin. I have not, except in one or two cases, used even artificial drains, which I think rarely necessary if the wound be dry and aseptic.

Before leaving this subject I will allude to a very common, although frequently overlooked, affection. A primary tuberculous infiltration of the bursa beneath the ligamentum patellæ. An indolent swelling, slowly enlarging, is seen to obliterate the sulci which naturally exist on either side of the ligamentum patellæ in extension of the limb. This sometimes interferes with complete extension or perfect flexion of the joint. Chances of contamination of the articulation or surrounding structures exist, or supuration may occur. In two cases in which I removed this bursa, its walls were immensely thickened by granulation tissue, and it contained a mucoid sanious fluid in its cavity. Removal can easily be effected by freeing the ligamentum patellæ from its attachments through an incision along its inner margin, slipping it over the growth to its external side, and by means of a blunt knife and curved scissors the latter may be removed.

I will now briefly allude to other varieties of hydrarthrosis to which I have applied the same remedy. It is satisfactory to be able to prefix the term synovitis by a qualifying adjective which will indicate its pathology, such as pyogenic, tuberculous, gonorrhœal, or rheumatic. But this is not always possible. A hydrops of intractable character will be found, which has arisen without obvious cause in an individual, otherwise in perfect health, has lasted for months, or even years, unaltered by treatment. There is no history of illness at the time of its invasion, no gonorrhœa, no enteric, no evidence of rheumatism, injury, small-pox, scarlatina, syphilis, or diphtheria. How do we explain its incidence? It is all conjecture. Such a case is the following, of which, through the kindness of my colleague, Dr. Haughton, I am able to show a picture.

I. T., a native of Roscrea, æt. 43, a coachman by occupation, was sent to me by Dr. Cooke. About two years ago, without any recognised cause, his knee began to swell. He never had any illness. His knee had been repeatedly blistered, and various liniments had been applied. A slight diminution of the swelling he believes occurred subsequent to the blistering, but he thought the enforced rest had a good deal to do with the improvement. He now suffers from a weakness of the limb, which interferes with his occupation. Even for the few days he had been in hospital his knee is reduced considerably in size. I operated on him some weeks ago in the manner before described. On opening the joint it was found to be filled with a straw-coloured liquid. This was saved to the extent of about 10 ozs. It was full of albumin and became a solid mass on exposure to heat, showing that it was probably a transudate and not an exudate. The interior of the synovial membrane presented a very rough appearance due to the presence of a number of small growths, some sessile, some peduncular. I removed

as many of those as I could reach with curved scissors, they were not vascular. I then used the pure carbolic acid and irrigation in the ordinary way. This man left hospital about ten days ago.

HYDROPS AFTER ENTERIC FEVER.

I. C., a soldier in the 2nd Bedford Regiment, was invalided very early in the South African Campaign with enteric. He had been incapacitated for five months with a large hydrops of left knee, and had, according to his statement, but three months left to rejoin his regiment or leave the service. I operated on him in March, 1901. Unlike some hospital patients, which, no doubt, some of us have met with, this poor boy had a generous anxiety to acknowledge his obligation, and wrote me two letters. I will read a sentence from each one. Date, May 16th: "You will be glad to hear my knee is keeping very well." Another, dated August 16th: "I am about to embark again for South Africa this month. My knee has quite recovered."

J. S., æt. 26, Roscommon. Hydrops of left knee. Operated on in Steeven's Hospital. Left for home well in six weeks. Cause obscure, ascribed to a wetting.

Jane M., æt. 22, an enormous hydrops of left knee, which had been indolent for eight weeks, but had lately taken on more acute features, with some pain and temperature. I suspected the presence of gonococci in this case, but our pathologist could find no positive evidence in the fluid removed. I used a very rigorous cleansing, and passing my fingers into the joint, evacuated its posterior regions and stripped the crucial ligaments and interior of the synovial membrane of a gelatinoid exudation before the application of the acid. She made a perfect recovery, and had now complete use of the joint.

Enough has been said to show that the proceeding, were it not even invariably followed by good results, is at least safe. My chief aim, as it was my primary idea, is to demonstrate the efficiency of dealing by this method with tuberculous hydrops not associated with disease of other parts than that in the synovial membrane. I admit the differential diagnosis is not always easy, as in many cases the joint affection by its prominence obscures the osseous focus which was its originator. I think, however, that uncomplicated primary synovial tuberculosis is more frequent than is the opinion of most writers on the subject.

A SUCCESSFUL CASE OF PYLORECTOMY:

PERFORMED IN TWO STAGES. (a)

By T. E. GORDON, M.B., F.R.C.S.I.,

Surgeon to the Adelaide Hospital.

OPERATING surgeons are by no means agreed as to the best method of performing pylorectomy, and some look with disfavour on the operation generally. Under these circumstances it seems right that operators should record their results, and thus add weight, however small, to one or other side of the balance.

A man, æt. 43, had suffered from vague gastric symptoms since August, 1899. Pain was never severe; vomiting was not constant, and for some time before coming to hospital he vomited very seldom. Since Christmas last his general health began to fail, and he lost one and a-half stone in weight. He came to the Adelaide Hospital in April, and was placed under the care of my colleague, Dr. Wallace Beatty. A tumour was found in the abdomen just above the umbilicus. It measured about three inches

(a) Read before the Surgical Section, Royal Academy of Medicine in Ireland, Jan. 17th, 1902.

in transverse diameter, was hard and irregular, and could be felt to move readily with respiration. One could move the tumour remarkably freely; thus it could be pressed to the upper parts of the epigastrium, downwards, so that its lower margin was below the umbilicus and to the right side well into the right hypochondrium. A divided seidlitz powder was given which demonstrated amoderate degree of dilatation of the stomach below the growth. There was no liver enlargement, and this fact together with the remarkable mobility of the tumour, and the man's condition of fair general health led us to hope that we might find an absence of adhesions, and of secondary cancer deposits.

On April 2nd, 1901, I opened the abdomen somewhat to the left of the middle line. After making a hasty examination of the tumour, which seemed to justify the hopes we had entertained, I turned upwards the transverse colon and performed a posterior gastro-enterostomy. I made the stomach opening as far over to the left as I could, and the method adopted was that of Roux. In this operation, it will be remembered, the jejunum is divided some distance from the duodenal flexure, the lower end is fixed to the stomach opening, and the upper end (of the cut jejunum) is made to anastomose with the jejunum again some four inches or more from the stomach junction. I used simple suturing throughout. The gastro-enterostomy completed I closed the abdomen, leaving the pylorotomy to be performed when the man should have recovered from this first operation.

After operation the course of the case was satisfactory. There was little or no shock, and he only vomited once, as he was recovering from the anæsthetic. I gave liquid nourishment, such as barley-water and whey, on the day following the operation, and he was able to take solid food by the ninth day. In rather less than three weeks I sent him for one week to a convalescent home.

On April 27th, *i.e.*, twenty-five days after the gastro-enterostomy, I again opened the abdomen. This time I made the incision to the right of the first one, and almost in the middle line. The incision was an ample one—quite five inches long. There were some slight adhesions behind the scar of the first operation, but they did not materially interfere with my work. When the stomach region was exposed my first step was to make an opening in the lesser omentum, through which I passed my finger to explore the posterior aspect of the tumour, and then to act as a guide in the division of the great omentum. This division was effected by cutting between pairs of Kocher's clip forceps. I now placed one Doyen's clamp forceps across the duodenum. I was unable to get on a second, for the readily available duodenum, *i.e.*, that within the lesser peritoneal sac, was very limited in extent. I cut across the duodenum, very little leakage occurred from the pyloric orifice, and then, at once, I sewed up completely the opening of the duodenum by two rows of silk sutures. This done, I cut the stomach across between clamps placed well beyond the apparent limits of the growth. The opening in the stomach was also sewn up by a double row of silk sutures. In closing the abdomen I left in the area of operation a gauze drain. Hæmorrhage during the operation was very small in amount, with the exception of a small bleeding which took place owing to the slipping of a ligature on the pyloric artery.

The operation lasted almost an hour and three-quarters.

The excised portion of stomach showed a considerable narrowing of the pylorus by a growth which proved, on microscopic examination, to be a columnar-celled cancer. The tumour ended abruptly on the duodenal side, but its limits in the opposite direction

appeared to the naked eye less definite. However, microscopic sections failed to demonstrate any cancer in the wall of the stomach at the level of the duodenum.

For some days after the operation, the patient remained in a very precarious state. His temperature on the second day was 102°, and his pulse was on one occasion, as much as 160. On the fourth day a considerable discharge of bilious fluid occurred from an opening at the lower end of the first incision; but the general condition of the patient had materially improved. At the end of the first week, however, he seemed to be losing ground. I decided, therefore, to risk a considerable increase in the amount of food taken by mouth, and I found he could take four pints of peptonised milk without any discomfort. Steady progress began and has continued. On June 2nd the patient weighed 9st. 4lbs.; on July 21st, 9st. 10lbs.; on October 6, 9st. 10lbs.; and on Nov. 27, 10st. 2lbs. He now feels well and strong, and is able to do some work every day. The biliary fistula has never completely closed, but this is probably due to the separation of the silk sutures which have from time to time been extruded from the fistula.

REMARKS.

Although there are many points in this case which call for criticism, I propose to confine my remarks to the consideration of one question, which, while it is of fundamental importance, is unfortunately still open to serious doubt. "Is pylorotomy under any circumstances legitimate?" In an endeavour to answer this question we must take two things into consideration—

1. The immediate mortality.

2. In case of survival, the prospect of long delayed recurrence or perfect recovery.

Some years ago the mortality was overwhelming, and even now we must regard pylorotomy as, perhaps, the most dangerous operation in all abdominal surgery. Still, if it can be shown that the operation holds out a reasonable prospect of ultimate success we need not be deterred from giving this chance to the patient through fear of its 30 per cent. mortality. Unfortunately in the very large majority of cases recurrence takes place, and that early. On the other hand, we find from year to year an increase in the number of recorded cases where patients have lived, or are still living two, four and even seven or eight years after the operation. How then shall we answer the question we have put before us? Is it sufficient to meet this 30 per cent. mortality and, let us say, 80 per cent. recurrence within three years, with the defence that the disease without operation is incurable, and hence each life saved is as a brand plucked from the burning? Or again, may we find comfort and justification in the reflection that pylorotomy is still in its infancy, and that the better results of these later years suggest hopefulness for still further improvement? My own impression is that if we cannot thus reasonably look forward to a better general record at the end of the next ten years than can be shown for the past ten, this operation is as certainly doomed as is splenectomy for leucocythæmia or thyroidectomy for exophthalmic goitre. I believe, however, that we may be hopeful, and I will devote the remainder of the time at my disposal to-night to a consideration of the lines along which we may look for improvement. The subject may be divided under two headings. First, improvement in selection of cases; second, improvement in operative technique.

1. Improvement in Selection of Cases:—I am convinced that pylorotomy should be employed only in cases which appear, when the abdomen has been opened, to be absolutely favourable. Where the

patient's general health and strength have been wrecked, where there are enlarged glands beyond the immediate vicinity of the growth, or where there are adhesions, the surgeon ought either at once to close the abdomen, or, if necessary, to perform a gastro-enterostomy. It may be said, "one never sees cases so perfectly favourable"; to which I would reply, "Then, in Heaven's name, never perform pylorotomy."

It is a fact which should be thoroughly grasped that cases suitable for this operation are exceedingly rare, and they will continue to be so until physicians recognise it as a duty to submit doubtful cases to an exploratory laparotomy. At the same time let us be reasonable in our judgments. Can we expect either physicians or patients to be enthusiastic while the results of pylorotomy are such as they are at present? Moreover, there is surely a limit to the application of exploratory laparotomy? With the present uncertainty of diagnosis it is clear that if physicians were to yield as they have been urged to do there would be performed many negative explorations. It may be that but little harm would thus be done to the individuals operated upon, but might not a very serious harm result to abdominal surgery generally?

So much for selection of cases. Let me now draw your attention to the operation itself.

The operation which I performed may be taken as an example of a pylorotomy in which the open ends of stomach and duodenum which result from the excision of the pylorus are sewn up and a new exit is provided by a gastro-enterostomy. This method has, it seems to me, several advantages. In the first place, with it recurrence of the cancer does not necessarily include recurrence of obstruction, for the opening between stomach and intestine is far removed from the area of disease. Again, the gastro-enterostomy will remain equally easy of performance whether the amount of stomach excised be great or little, of course within certain limits. This is a matter of no small importance, now that surgeons have begun to apply to pylorotomy the same principle which guides them in, let us say, amputation of the breast, i.e. to carry their incision or dissection far beyond the apparent limits of disease. On a liberal application of this principle depends mainly the prospect of improved *ultimate* results in this operation, and it is because the method of operation we are considering *facilitates extensive excisions* that I have thought it right to give to it this prominent attention.

I wish now to say a few words concerning the advantage of performing the operation in two stages. The principle which underlies it is that of substituting for one very dangerous operation two of lesser risk. The method is comparatively new, and the number of recorded cases small, but it has already the support of many of the best operators, and the results have been remarkably good. This change in technique aims at a reduction of the mortality of pylorotomy, and if it attains this end the first step towards better things will have been accomplished.

There remain many points of detail in my operation which will suggest criticism, but I have thought it best to confine my remarks to broader questions.

In concluding, let me briefly summarise—

1. The present position of pylorotomy is unsatisfactory, but there is no cause for despair.

2. That an advance may be made, it is, in the first instance, necessary to *reduce the immediate mortality*. This is to be done by (1) a more careful selection of cases, and (2) by performing the operation in two stages.

In the second place, it is necessary to *obtain better ultimate results*. The way to this end lies in (1) wider resections, and (2) in this case also in better selection of cases.

3. Let these things be accomplished and we may then, with more justice than at present, call upon physicians to resort more frequently to exploratory operation.

SUBPERITONEAL HYSTERECTOMY. (a)

By J. A. MANSELL MOULLIN, M.B.,
Oxon, M.R.C.P., Lond.,

President of the British Gynaecological Society, Physician
to the Hospital for Women, Echo.

THE operation involves very considerable detail and although the opening of the abdomen and the amputation of the tumour need not in a favourable case occupy a practised hand many seconds, yet that constitutes but a very small part indeed of the operation. A mere display of rapidity, as represented by the cinematograph, has nothing whatever to commend it but the applause from the gallery.

When the tumour has been raised out of the pelvis and the lower segment of the uterus is not involved in the growth, nothing is more simple than to find the arteries on either side, and I am conservative enough to prefer to see them and secure them with a trifle of silk, to any process of crushing needing for the purpose a special instrument better adapted to all appearance to the requirements of the veterinary surgeon, or perhaps the farrier.

Having secured the ovarian vessels with a double ligature, I cut between them and extend the incision as far down as need be through that portion of the broad ligament which is free from vessels, and then carry it across the face of the tumour to the opposite side, above the bladder, which is stripped down and pushed out of the way. The uterine artery is then secured on either side with a single silk ligature passed as close to the cervix as possible, and a clamp placed over the ligature. If the ligature should not have secured the artery efficiently, the clamp will do so, and it further enables my assistant to hold the stump more securely while I cut away the tumour. It is of importance not to complicate matters by the use of unnecessary ligatures and clamps—the fewer the better.

The amputation of the tumour should be at the lowest level possible. The reasons for this are obvious. The stump is smaller and more neat, there is less trouble from hæmorrhage, and the trunk of the artery will be found secured in the clamp and cut below the point at which it commences to divide into the substance of the uterus. There is no necessity to strip the peritoneum from the back of the uterus, to which it is closely adherent, in order to make a posterior flap. I bring the cut edges of the stump into careful apposition with deep and superficial sutures of chromicised catgut, and then draw the anterior flap and the bladder well over the face of the stump and fasten it with a continuous suture of fine catgut from one side of the pelvis to the other. These constitute the steps of what may be termed a straightforward operation. The size of the tumour does not necessarily complicate the operation, but difficulties arise when the tumour cannot be raised out of the pelvis, when the lower segment of the uterus is enlarged by the growth, when the tumour follows some anomalous course and burrows under the pelvic peritoneum, or between the layers of the mesentery or meso-colon, or when some inflammatory trouble, generally due to co-existent disease of the appendages, has resulted in endless adhesions.

The resourcefulness and experience of the operator are then put to the test, and every difficulty has to be met as it occurs. It may be the restraining bands

(a) Abstract of Valedictory Address before the British Gynaecological Society, January 8, 1902.

are the broad and round ligaments, and when these have been divided and stripped down the tumour can be raised. If the uterine arteries can be secured it may be advantageous to remove the upper portion of the tumour before dealing with the lower segment. On several occasions I have successfully divided the lower part of the uterus vertically, either posteriorly or anteriorly, and have thus been enabled to enucleate another separate tumour from the cervical region. Much of the superfluous capsule can afterwards be removed and a very neat stump eventually secured. The ureters in this operation are fairly safe when the bladder has been well stripped down and pushed out of the way. At any rate, it has been my good fortune not to have experienced any difficulty in this respect, although on more than one occasion the gaping mouth of some vessel has caused a passing anxiety. If discovered at the time I believe the simplest and safest operation is to fasten the end into the roof of the bladder.

All the steps above described take time, but I am sure it is not wasted. The after success of the case and the future comfort of the patient depend not only upon a complete asepsis which I take for granted, but also upon the perfect fulfilment of all these minutiae which distinguish the work of the practised operator. A line of suture is all that remains in the peritoneal cavity when the wound is closed.

And now a very important part of the operation remains to be completed—the closure of the abdominal incision, which in these cases is necessarily a long one. I shall briefly give you my views on this matter. The strength of the abdominal parietes depends entirely upon the fascia or aponeurosis. It is, therefore, essential to secure an accurate adaptation and firm union of the cut margins of this, the middle layer. Any failure to do so inevitably results in the formation of a hernia. You must bear in mind that the aponeurosis splits to form the sheath of the rectus muscle on either side. In the lower two-thirds of its extent that layer is strongest which lies in front of the rectus muscle, but in the upper third the strongest layer lies behind the muscle. In the lower two-thirds the peritoneum is separated from the aponeurosis by a large quantity of cellular tissue and subperitoneal fat, while higher up and above the level of the umbilicus this cellular tissue and fat disappear, and the peritoneum is closely applied to the fascia. Consequently, I adopt a different mode of suturing in these two regions. In the lower part, which is invariably the seat of hernia, when it occurs, I sew the three layers, peritoneum, fascia and skin, separately. First, the peritoneum with a continuous suture, then the fascia with interrupted sutures, and finally the skin with another continuous suture.

In the upper region, when there are only two layers, and consequently it is quite unnecessary to make a third, I suture *en masse* with silkworm gut. The inner layer, composed of peritoneum and fascia, and the outer layer of skin, are in the nature of things bound to unite, and no better mode of suturing can be desired.

For buried sutures I always employ fine chromicised catgut, finding from experience that it can be rendered perfectly aseptic. Moreover, it possesses that most essential quality for a buried suture—it lasts sufficiently long to permit the tissues to become firmly united, and then itself becomes absorbed, approximately in about three weeks' time. Since adopting this mode of suturing I have not had a single case return with a weak scar. Silk I have long discarded, as quite unreliable. At the present time I have a patient under observation who underwent what was considered a brilliant and most successful operation at the hands of one of the surgeons at Guy's, and who two years afterwards is still engaged in trying to extract the bits.

And now I wish to say something on the subject of the repair of hernia when it occurs in an operation scar. The object to be aimed at is the restoration of the parts to their original condition—to find and bring together the edges of the middle layer or aponeurosis, which for some reason have failed to unite, and have retracted, becoming shut off by the union of the peritoneum with the skin, these two layers alone forming the covering of the hernia. I first carefully open the skin at its thinnest part, taking care not to injure the bowel, which is often adherent beneath. The hard margin of the opening, easily felt before commencing the operation, unaccountably disappears, and in order to find the fascia it is necessary to carry the incision upwards and downwards through the whole extent of the rupture and into the sound structures beyond. Here the aponeurosis is readily discoverable, and turning the flaps up I divide the peritoneal surface with the scissors (those used for the perineal operation are the best), and open the sheath of the rectus, starting from the aponeurosis in the lower part of the incision, and carrying it round to that in the upper. After carefully removing all old scar tissue, and freshening the edges of the aponeurosis, I bring them together with chromicised catgut in the manner already described. I have had good results, and some of the cases are still under observation.

Clinical Records.

THREE CASES OF MYOMA UTERI. (a)

By F. BOWREMAN JESSETT, F.R.C.S.

Miss P., *æt.* 43, has had inguinal hernia on the left side since twenty-four years of age, and on the right side for five years. She has been treated for uterine displacement for eight years, and two years ago was treated for peritonitis and appendicitis. She has suffered considerable pain and irritation of the bladder for some time past, and has also had a foul vaginal discharge.

On examination the left hernia is very pronounced; the right not so apparent. A distinct tumour is felt over the pubes and extending to the right side. Bimanually:—The uterus is enlarged considerably and fairly movable. There is fulness in the left vaginal fornix.

Operation.—On December 9th I performed abdominal hysterectomy. There were a great many adhesions in Douglas' pouch, more particularly on the left side. The myomatous uterus was delivered with difficulty by means of Doyen's screw. It was then found that the chief tumour was situated in the right broad ligament, and it was removed by enucleation, the peritoneum having been first divided. The ovarian and uterine arteries were then ligatured, the uterus drawn out and a cyst of considerable size found in the left broad ligament. The uterus with its myomata were removed, and the cyst enucleated. On examining the left hernia a large portion of omentum was found to be strongly adherent to the sac. It was ligatured and divided, and the inguinal opening stitched over with a view to radical cure. The abdomen was finally closed in the usual manner. The patient suffered for three days from most violent anæsthetic vomiting, but has made a good recovery.

CASE II.—A. T., *æt.* 48, married twenty years. Six children; last born six years ago. Patient states that she noticed a swelling in the abdomen about two years ago, and it has gradually increased in size since. During that time she has suffered from a dragging pain in the left side, extending down into the leg, and gradually increasing in severity. There had been some difficulty in defæcation for twelve months, and there had been frequency of micturition unaccompanied by a sense

(a) Cases exhibited before the Brit. Gynecological Society, Jan. 9th, 1902.

of relief for two years. Menstruation regular up to date of admission.

Examination.—Three distinct mobile tumours can be definitely made out, occupying the iliac and umbilical regions.

Operation.—On opening the abdomen a large tumour at once presented itself. The left tube was drawn completely over it and disappeared behind it. The tumour was readily delivered by means of a Doyen's screw. I secured the uterine artery on the right side, but could not define the uterus. The tumour was evidently situated in the left broad ligament. I divided the peritoneum, stripped it off the tumour, and enucleated the latter. The uterus was then discovered deeply embedded in the pelvis, and completely enveloped in the tumour. I ligatured the uterine arteries, and divided the cervix. I experienced some difficulty in stitching the pelvic peritoneum over it owing to the extreme fatness of the patient, but with the exercise of much patience succeeded in neatly doing so. The patient made an uninterrupted recovery.

CASE III.—L. A., *æt.* 43, had suffered from hæmorrhage for about a year, and it had much increased of late, indeed the hæmorrhage was often alarming.

On examination a soft tumour the size of a cocoon was found occupying the uterus, this had increased a good deal in size of late.

Operation.—On January 6th I performed sub-peritoneal hysterectomy. No difficulty presented itself. The tumour proved to be a huge submucous myoma. I preferred removing the whole uterus to enucleation, as often the latter method involves considerable hæmorrhage, and in the enfeebled condition in which the patient already was, I did not think it wise to run the risk of any great loss of blood. Moreover, it had been pointed out by some observers that mono-tumours were occasionally malignant.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, JAN. 24TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

CLINICAL EVENING.

CASE OF BILATERAL FACIAL PALSY.

DR. SKYMOUE TAYLOR showed a lad, *æt.* 15, who had "paralysis of the legs and arms at five," from which he recovered. He had never been able "to move his face." No history of delivery by forceps or otorrhœa, but he had had two attacks of rheumatic fever followed by valvular disease. The lad exhibited almost complete bilateral facial palsy; but there was slight voluntary power in the risorius and the depressor anguli oris, and also in a few fibres of the orbiculari-oris muscles. He talks readily, but all labial and explosive consonants are pronounced by the aid of the tongue, so that "apple" is turned into "attle," "pear" becomes "tear," and so on. No sign of degenerative changes in any other nerve. The exact seat of the lesion has not yet been determined by complete electrical reactions, but the probability was in favour of the lesion being peripheral.

CASE OF DISLOCATION OF NAVICULAR.

MR. G. TURNER showed a man, *æt.* 32, who fell from his horse, crushing his left foot; in getting on to his feet he twisted his foot inwards, after which he could not put his foot to the ground. When he came up to the hospital there was a prominent rounded swelling just below and in front of the internal malleolus of the left leg. This swelling was quite easy to reduce by inverting the foot and pressing the swelling outwards but it returned when the pressure was relaxed. There was rather a marked hollow below the external malleolus, and decided abnormal mobility at the mid-tarsal joint. Under the X-rays the scaphoid was seen to be dislocated inwards. The foot was put up in a thickly padded internal splint so as to maintain it in a position of inversion, but it was found impossible to keep the dislocation

thoroughly reduced. Massage and movement were commenced after the first five days, and the patient got up and walked about with crutches in two weeks. He left the hospital, walking without crutches, on November 30th.

BILATERAL CERVICAL RIBS, AND AN ABNORMAL BONY MASS AT THE FIRST CHONDRO-STERNAL JUNCTION.

MR. LAWRIE MCGAVIN showed a girl, *æt.* 18, who first noticed a mass under the left clavicle six months ago, which had given rise to no inconvenience except from time to time aching pains in the region. On examining her the condition of her neck was accidentally discovered. She had lately complained of slight numbness and tingling over the dorsum of the first and second metacarpal bones of both hands. In addition to this she had occasionally experienced shooting pain in the area of distribution of the superficial branches of the cervical plexus, especially of the great occipital and supra-acromial divisions. The symptoms were more marked on the left than on the right side. The position of the supernumerary ribs was demonstrated on a skiagram; that on the right side was short and straight, and ended over the centre of the first rib, springing from the transverse process of the seventh cervical vertebra. That on the left was curved, and, springing also from the same point, appeared to end much nearer to the inner end of the clavicle. The sternal extremities of the first ribs were markedly different in shape, that on the right being broad and thick, while that on the left thin and indistinct. At the upper margin of the skiagram is seen an indistinct nodular bony mass, apparently in connection with the transverse processes of the fourth and fifth cervical vertebrae.

A CASE OF ABNORMAL CURVATURE OF THE SPINE DETERMINED BY SHORTENING OF THE LEFT RECTUS ABDOMINIS MUSCLE.

MR. J. JACKSON CLARKE showed a female child, *æt.* 9, first seen in December, 1900. She then had a pronounced C-shaped total kyphosis, associated with slight dorsal scoliosis, the convexity of the curve being to the right. The patient's breathing was purely abdominal, and the abnormal curves in the spine were fixed, not disappearing either when the patient lay down, or when manual pressure was employed. On attempting to straighten the spine, he observed that the lower portion of the thoracic wall on the left side was dragged upon, and that the left rectus muscle was tense and hard in every position of the body, and that it was less resistant when the patient was sitting with the body bent forward than it was when she lay down on the back. On inquiry he found that when the patient was six months old her mother had noticed that the right side of the abdomen was more prominent than the left. The case was probably akin to the common form of wry-neck, due to organic shortening (contracture) of one sterno-mastoid in infants. The treatment has been instrumental and gymnastic. Improvement has been thus obtained through the stretching of the shortened rectus; it remained to be decided whether any marked gain would result from elongation of the left rectus by the simple plastic operation by Z-shaped incision. There was no abnormal reflex. In the absence of progressive myositis, &c., he concluded that the origin was congenital.

ARTHROPATHY OF SHOULDER-JOINT IN A CASE OF SYRINGOMYELIA.

MR. W. HARMER showed a man, *æt.* 20, who had sustained an injury to left shoulder twelve months previously, followed by a swelling (? ruptured muscle), which gradually subsided. Eight months ago a painless swelling of same joint occurred, commencing suddenly without injury. This was followed by two months' grating and "shifting of bone." "Back curved" last three or four years. No history of syphilis. Generally has boils on some part of body. Short, strongly built patient; voice always husky. No muscular wasting discovered. Grip in left hand a little weaker. Left shoulder-joint uniformly enlarged (18 inches by 15 *Et.*), painless. Movement free as high as the level of acromion process, but attended with marked grating and luxation. Head of humerus eroded. When arms are

hanging there is an inch of lengthening of left due to laxity of ligaments. Well-marked kyphosis and lateral curvature with convexity to the left. Not tender on pressure. Secretion of sweat excessive on face. Numerous painless ulcers on thumb and fingers of left hand, commencing as bullæ. Complete thermo-anæsthesia from about fifth cervical to third lumbar spines, including arms. Analgesia marked only over front and lateral aspect of joint; slight in left hand. Tactile sense normal. No loss of muscular pressure or localisation senses. Knee-jerks marked. No ankle-clonus. No ocular changes.

Dr. LUND referred to a similar case in a man, æt. 52, under his observation for ten years. There was a history pointing to chronic pyæmia.

A CASE ILLUSTRATING A NEW METHOD OF TREATING OLD-STANDING PARALYSIS OF THE UPPER ROOT OF THE BRACHIAL PLEXUS (ERB-DUCHENNE TYPE).

Mr. A. H. TUBBY and Dr. PURVES STEWART showed a heavy man, æt. 57, who two years ago fell on to his shoulder and head. He was unconscious for an hour afterwards, and on recovery was unable to use his left arm. After treatment at various hospitals without benefit, he was admitted to Westminster Hospital under Dr. Murrell. There was then marked paralysis and atrophy about the left shoulder and upper arm, and Dr. Purves Stewart reported total loss of electrical excitability in the deltoid, infraspinatus, biceps, brachialis anticus, and supinator longus on the left side, and consequent inability to abduct the arm or flex the elbow. There was also some anæsthesia along the outer side of the upper arm and forearm, which subsequently disappeared. These symptoms pointed to a paralysis of the upper root of the brachial plexus of the Erb-Duchenne type. On June 2nd, 1901, he was transferred to the care of Mr. Tubby, who on June 6th, twenty months after the accident, with the object of restoring the power of flexion at the elbow, transferred part of the triceps and fixed it into the biceps. On July 1st an attempt was made to restore power to the deltoid. Since the operation the transplanted portions of muscle have been assiduously massaged and the faradic current applied. There has been great improvement in the movements and utility of the limb. He can flex the elbow fairly, and during flexion the transplanted part of the triceps can be felt in front of the elbow, and both galvanic and faradic excitability have returned. The patient has not yet recovered the power of abducting the arm, but the transplanted part of the pectoralis major can also be felt to harden. At first there was a total loss of excitability both to induction shocks and to the galvanic current. Three months after operation the galvanic excitability returned, and six months after faradic reaction could be demonstrated.

COXA VARA TRAUMATICA, WITH SKIAGRAPH; INSIDIOUS ONSET.

Mr. HAROLD L. BARNARD showed a child who had come under his observation with the characteristic signs of coxa vara. On questioning the mother he found that, eighteen months before, the child had complained of pain in the hip, and for three days had been unable to walk at all. Then he began to walk again, but the following year he commenced to limp. The signs were definitely those of coxa vara, viz., abduction was very much limited, internal rotation also very limited, while flexion and adduction were free. No pain was complained of in the joint or on movement. The treatment so far had been a Thomas's knee-splint to keep the weight off the hip-joint, the mother objecting to any operation. The child had suffered from blood spitting.

Mr. BARNARD also showed a patient who had compound fracture of patella. This he had sutured with kangaroo tendon, followed by suppuration and drainage of the knee-joint; bony union and good movement resulting.

TRAUMATIC SEPARATION OF THE EPIPHYSIS OF THE HEAD OF THE FEMUR DEMONSTRATED BY SKIAGRAPHY.

Mr. J. HUTCHINSON, jun., showed a lad, æt. 17, who was admitted into the London Hospital on November 22nd, 1901. He had had a fall, with, probably, forced

extension and eversion of the right hip. He was unable to walk, and complained of intense pain on passive movement of the right thigh. The latter was everted as in most cases of impacted fracture of the femoral neck, anterior dislocation, &c. There was no bruising over the trochanter, and no abnormal fulness in Scarpa's triangle. The right ilio-tibial band was slightly relaxed, but yet no shortening could be made out. Pressure on the trochanteric region did not cause pain. The Röntgen rays showed very plainly a separation of the femoral head exactly at the epiphysal line, the epiphysis remaining in the acetabulum, and being only in contact with the femoral neck to about half the normal extent. Under an anæsthetic the limb could be freely moved in all directions, and a faint sort of crepitus was obtained. The eversion could easily be overcome, but when the extension was taken off the deformity at once recurred. The limb was put on a Liston's long splint, and almost perfect apposition was obtained. Until the introduction of the X-rays, positive evidence as to the occurrence of traumatic separation of this epiphysis was singularly scanty.

MAJOR DILATATION OF THE LEFT AURICLE.

Dr. W. EWART showed a patient who presented the following distinctive physical signs:—1. *Palpatory*: the definite systolic pulsations in the right mammary region, and the occasional thrill perceived there as well as at the apex; and lastly, the occasional pulsation of the liver. 2. *Auscultatory*: the identical character of the murmur in both mammary regions, whilst in the interval between them and at the aortic interspace the systolic murmur, though easily perceptible, was much less loud; and the presystolic murmur, which, however, in this case was of inconstant character. 3. *Percussory*: the tracings exhibited show the conditions which served as a basis for the diagnosis. *Anteriorly* the cardiac dulness was much enlarged in its transverse diameter, and somewhat also in its vertical diameter, the liver being depressed as well as slightly enlarged; whilst at the base there was no dulness suggestive of an aneurysm. The left cardiac boundary, although further out than normal, presented no irregularity; and the right boundary did not differ much from that of a greatly enlarged right auricle. But *posteriorly* the dulness was characteristic. The dulness belonging to the heart was slightly enlarged; but that special to the left auricle was, as might be seen in the tracings, considerably increased (from a normal size of about 2½ inches by 2 inches to that of nearly 4 inches by 2½ inches), mainly in its transverse diameter, and in the direction of the seat of abnormal pulsation, which by auscultation was identified as belonging to the left auricle.

CASE OF EXCISION OF THE CÆCUM.

Mr. ARTHUR BARKER showed a man, æt. 30, who was operated on for acute intestinal obstruction on May 7th, 1899. The enormously distended and hypertrophied small intestine was first incised, and five pints of liquid feces were evacuated. The cause of the obstruction could then be made out to be a hard growth round the ileo-cæcal valve. The small gut, at about two feet from its termination, was therefore anastomosed laterally with the transverse colon. Six weeks later a fresh incision was made over the cæcum, and the latter was excised with some inches of the ascending colon and ileum. Beyond the presence of a slight fecal fistula for some weeks, recovery was perfect. The patient is now in excellent health, without any evidence of recurrence two years and eight months after operation. The growth was a typical carcinoma.

CASE OF EXCISION OF TRANSVERSE COLON.

Mr. BARKER also showed a woman, æt. 58, who was operated on for carcinoma of the transverse colon and chronic obstruction on October 25th, 1900. She was suffering at the time from long standing diabetes. About four and a half to five inches of the transverse colon were removed, and end to end anastomosis followed. The dressings remained untouched for ten days. On their removal a small fecal fistula was found, and discharged for some weeks with one of the suture threads, probably omental. Recovery was otherwise

uneventful. The growth was typical carcinoma. The patient has been in first-rate health ever since, and shows no evidence of recurrence.

A CASE OF ATAXIC PARAPLEGIA.

Dr. NORMAN DALTON showed a man, æt. 52, who contracted syphilis two years ago. On admission had ulcers on the legs which are nearly healed. His present symptoms had been coming on about one year ago. His mind is sound, but he is emotional and excitable. His symptoms were partly those of locomotor ataxy and partly those of lateral sclerosis. The eyes and the upper limbs are normal. As a rule he stands fairly steadily with his eyes shut. He complains of "precipitate" micturition and defæcation. In "walking" he brings his foot down forcibly on the heel as in staxia; but he does not lift the knees, and the legs appear to be affected by a certain amount of stiffness. The muscles of the legs and thighs are rather flaccid. Their electrical reactions are normal. The "knee-jerks" are greatly exaggerated, particularly on the left side, and ankle-clonus can be obtained always in the left foot. The plantar reflex is of the extensor type. No delayed sensation. He has complained of pains in the left leg, shooting from the hip to the foot, sometimes accompanied by twitching movements. In the right lower limb, as high as the crest of the ilium (back and front), there is loss of painful sensation, and of sensations of heat and cold. The sense of touch is retained, and the sole of the foot is very sensitive to touch. There is no loss of the sense of position of the lower limbs. There has been no definite crisis, but he has had pains in the hypogastrium.

A CASE OF CONGENITAL SPINAL DEGENERATION WITH SYMMETRICAL ARTHROPATHY.

Dr. ESSEX WYNTER showed a young man, æt. 17, who was kicked over the left eye by a horse at fourteen. Two years ago difficulty was experienced in walking, then it was noticed that the right hip was stiff. In May, 1901, the left hip was similarly affected, and by June there appeared to be no movement at all in either. On admission on December 9th, 1901, both hips were completely fixed in a fully extended position. There was some enlargement on the right trochanter. Measurement from the anterior superior spine to the internal malleolus 33½ inches on either side. Both trochanters are below Nélaton's line. Bryant's line—left 2½, right 2½ inches. No wasting or loss of sensation or muscular power. Electrical reactions normal. Reflexes uniformly exaggerated. The patient stands in a peculiar attitude, with knees slightly flexed, and the spine curved forward. He walks by rotating the pelvis and spine. After fourteen days' treatment by iodide of mercury there is some movement in the left hip; urine normal; temperature normal.

BRITISH GYNÆCOLOGICAL SOCIETY.

ANNUAL MEETING HELD JAN. 9TH.

J. A. MANSELL MOULLIN, M.A., M.R.C.P., President, in the Chair.

The Treasurer's report was presented and adopted on the motion of Dr. Heywood Smith, seconded by Mr. Bowreman Jessett. A vote of thanks to the treasurer, Dr. Travers, was carried at the same time. The report of the Editor of the *Journal* was then read. Dr. Macnaughton Jones in proposing its adoption alluded sympathetically to the absence of the Editor, Dr. Macan, through illness.

SPECIMENS.

Dr. F. A. PURCELL exhibited a

FIBROMYOMA OF THE UTERUS,

which had undergone necrosis, removed by abdominal celiotomy.

The patient, a single woman, 43 years of age, had noticed a lump, the size of a walnut, in the left side about eight years previously. This had gradually increased in size. Her general health remained unaffected, and she had suffered from neither constipation

nor indigestion. Menstruation had been regular till within three months of admission, though always accompanied by pain, and usually by sickness. During these three months the pain had for the first time increased, the catamenia had become excessive, the last two periods being separated by a week only, and the patient had to pass water about every three hours during the day and twice at night. On admission the centre of the abdomen was occupied by a large kidney-shaped mass, the two sides of which could be moved separately to a slight extent. The tumour felt semi-cystic on its upper surface and left side. Below and to the right side there was a smaller mass, separate and tender. *Per Rectum*.—A large immovable mass could be felt completely filling the pelvis proper. The condition of the hymen precluded vaginal examination. *Operation*.—On November 27th the abdomen was opened in the middle line. No adhesions were found. The upper, apparently cystic, portion of the tumour was tapped, and the tumour after some difficulty was brought out. A cyst of the right broad ligament was found and enucleated, and the uterus with the tumour removed. The interesting points in connection with the specimen were the presence of a hydrosalpinx in the right broad ligament and the formation of what appeared to be two distinct cystic cavities surmounting the solid portion of the fibromyoma, the upper surface of which was covered with a thick layer of lymph, caused by the friction between it and the stomach. *On section* it became evident that the tumour was not cystic, but that its upper portion had become, owing to necrotic degeneration, converted into a cavity filled with fluid and necrotic tissue. The pelvic portion, though solid, was also necrosed.

Mr. F. BOWREMAN JESSETT showed three cases of

MYOMA UTERI,

full description of which will be found under the heading of "Clinical Records."

Mr. MANSELL MOULLIN then delivered his valedictory address, in which he referred more especially to his personal experience in the performance of

SUBPERITONEAL HYSTERECTOMY,

an abstract of which will be found in another column.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SURGICAL SECTION.

MEETING HELD AT THE ROYAL COLLEGE OF SURGEONS, ON FRIDAY, JAN. 17TH, 1902.

The President of the Section, Mr. THOMAS MYLES, in the Chair.

LIVING EXHIBITS.

Mr. HENRY GRAY CROLY showed (a) Case of amputation at hip-joint; (b) Case of ligation of external iliac artery for ilio-femoral aneurysm; (c) Patient showing result of excision of head of humerus for unreduced intra coracoid luxation.

Mr. R. F. TOBIN showed (a) Patient, æt. 80, from whom the prostate was removed by enucleation (with specimen); (b) Case of excision of knee.

Mr. D. KENNEDY showed remarkable case of deformity of legs, due to rickets.

Mr. R. L. SWAN read a paper on

THE SURGICAL TREATMENT OF CHRONIC SYNOVITIS.

which will be found on page 102 under the heading of "Original Communications." In the discussion that followed,

Mr. MYLES said he was accustomed when a student to look on a knee-joint as the most dangerous cavity in the body. Even now he thought the old humoral pathology exerts a certain influence on our practice. He quite agreed with Mr. Swan that the proper treatment for such cases is opening the joint, and by so doing the pathological lesion will be made plain. In the majority of cases it consists in pedunculated growths commencing from the alar ligaments. If on opening the joint, especially in children, he found the synovial membranes to be tuber-

culous, he recommends that they be dissected out, a procedure which he believes leads to recovery.

Mr. E. H. TAYLOR objected to section of the patella. It leaves two raw osseous surfaces apt to be infected by tubercle, if any there be. He prefers Kocher's method, the flap gives room enough to examine joint. Free swabbing with strong carbolic acid devitalises the synovial membranes and the cartilage, and leaves them a prey to the tubercle bacilli in their vicinity. He looks on the method suggested as one not well calculated to give good results in hydrops articuli; the wound heals, but after a little time the limb becomes shorter and often flexed. There is not true ankylosis. He recommends that the hyaline cartilage be shaved off the bone and the raw osseous surfaces be joined, ensuring a sound limb.

Mr. H. G. CROLY said, as he understood, Mr. Swan's paper dealt with chronic synovitis, such as they so commonly meet with after an acute attack. They were not dealing with treatment of tuberculous or other forms of knee-joint disease by excision; but the question was the treatment of hydrops articuli. He had seen good results from aspiration in such cases, and must say that he had seen rest give good results. Many cases he believes call for such treatment as Mr. Swan suggests; but he would not approve of dissecting out the membranes and slicing off the hyaline cartilage.

Mr. TOBIN said he had tried the rest cure with hydrops articuli for months without getting any good results. He regarded the thick pulpy synovitis—Brodie's pulpy degeneration of the knee-joint—as tuberculous synovitis, though in specimens submitted to microscopic examination no bacilli were found. The result of opening the joint and dissecting out the membranes is sometimes very good and at other times very bad. Long-continued effusion has stretched the ligaments, and they are unequal to the strain of active life. Favourable cases give good results with movable joint, but the more uniformly good results are obtained by ankylosis following excision.

Mr. JOHNSON said that his experience of synovitis was not fortunate. He admitted a man with hydrops articuli which benefited for a time under the rest treatment, but the swelling did not wholly disappear. He opened the joint, irrigated it, closed it. The fluid removed, about ten ounces, was examined and found to be highly albuminous. Mr. O'Sullivan found that the synovial membrane contained bacilli in large numbers. His incisions, one on each side of and parallel to the patellar tendon, healed quickly and well; but they broke down in a week, and not long after the patient developed tuberculous meningitis, of which he died.

Mr. HAUGHTON considered that surgeons should no longer be in doubt as to the condition of the osseous tissue in tuberculous disease of the knee-joint, as the Röntgen rays give a clear representation of any rarefaction of the tissue that may be present.

Mr. LENTAIGNE asked Mr. Swan to describe his method. He had been for years using strong carbolic acid (absolute phenol) in different cavities of the body, tuberculous joints, after excision and after excision, and tuberculous sinus, &c., without seeing any evil effects from its use. As a student he had frequently met cases of carbolic poisoning, now he never sees one, although much larger quantities of carbolic acid were employed. He ascribes this to the carbolic acid they now get being pure; the toxic action was probably due to some impurity. He swabs out cavities with a very small sponge, held in a sponge-holder, and well wet with the liquefied carbolic acid, and has had no reason to regret it in any case. He thought Mr. Swan's operation might prevent the need for arthroectomy or excision.

Mr. DOYLE would like to know how Mr. Swan applied the carbolic acid; applying it on a swab is a most dangerous method. In children he has had bad results from operative interference with the synovial membranes of the knee-joint. The results are good for a month or so, but in three or four years' time they are found to be greatly deformed. Kocher's method gives great facility for examining the joint. He found the

locus of infection to be at the attachment of the crucial ligaments.

Mr. SWAN replied that he did not deal with excision or erosion in his paper. He had no concern with them. The object he had in view was to show the possibility of opening the joint, removing the fluid, and allowing the synovial membrane to return to its normal condition. Latterly he is not in the habit of cutting through the patella, but he cannot see the difference, as far as infection is concerned, between a cut in hard and one in soft tissues. Puncturing is perfectly safe if carried out aseptically. The subcutaneous bursa was not mentioned by him simply because it communicates with the synovial sac, and in all operations on the joint must be dealt with. This is not the case with the bursa under the patellar ligament, consequently he referred to it. He cannot agree with Mr. Tobin that portions of cartilage and bone are readily removed during the subsequent attempts at passive motion. Mr. Johnson got very bad results, but he took no precaution to avoid them; no bactericide was used, and the subsequent attack of tuberculous meningitis was a result that he thinks might have been anticipated after a tuberculous joint was opened. Tuberculous dissemination, as Owen pointed out, was, under the circumstances, a not infrequent sequence. He cleans out the joint with an aseptic loofah, and applies the carbolic acid with a stick. He is not wedded to carbolic acid; any equally powerful bactericide would answer quite as well.

Mr. GORDON read a paper on

A SUCCESSFUL CASE OF PYLORECTOMY, which will be found on page 103.

Mr. MYLES begged to heartily congratulate Mr. Gordon on the first successful pylorectomy performed in Dublin. The difficulty of diagnosing tumours of the stomach was very great. In one of his cases he cut down on the viscus with the intent of doing a pylorectomy, but found so much thickening of the gastric walls with what he and his friends thought was cancer that he returned the stomach unopened to the abdomen, and the woman is to-day, after some years, alive and well.

Mr. SWAN congratulated the author of the paper on his great success.

Mr. E. H. TAYLOR drew attention to the anatomical condition found in the duodenum close to the pylorus. Surgeons before beginning a pylorectomy he thought would do well to examine it.

Mr. JAMESON JOHNSON spoke, and

Mr. GORDON having thanked the members for the kind reception his paper received, the meeting adjourned.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, JAN. 16TH, 1902.

Dr. D. B. LEES, the President, in the Chair.

At the annual meeting of the Society the following gentlemen were unanimously elected officers of the Society for the year 1902:—President, Mr. W. Watson Cheyne; Vice-Presidents, Dr. H. A. Caley, Dr. F. W. Cock, Mr. J. Jackson Clarke, and Dr. L. Guthrie; Treasurer, Mr. Edmund Roughton; Hon. Secretaries, Dr. Edmund Cantley and Mr. Francis Jeffrey. Council: Dr. Edgar Bulleid, Dr. C. Buttar, Mr. H. S. Collier, Dr. A. Eddowes, Mr. Raymond Johnson, Dr. D. B. Lees, Dr. H. J. Macevoy, Mr. Hubert C. Phillips, Dr. Risien Russell, Mr. Sefton Sewill, Dr. G. A. Sutherland, Dr. James Taylor.

The Reports of the Council and the Treasurer showed that the number of members exceeded 400, and that the Society had a balance of over £125. Votes of thanks to the President, the Treasurer (Mr. Edmund Roughton), and the Secretaries, especially the retiring Secretary (Mr. Hubert C. Phillips), for their valuable services during the year were carried and suitably acknowledged.

The President, Dr. D. B. LEES, delivered an address on

THE HEART OF THE CHILD.

He drew attention to the importance of the subject, which he thought was much neglected. He gave some

details of the method of physical examination in the case of children, and laid special stress on the importance of light percussion, and on the desirability of postponing auscultation until the size and strength of the heart had been carefully ascertained. The necessity for accurate determination of the size of the right auricle, by percussion in the third and fourth right intercostal spaces, in all acute pulmonary affections, and in disease of the left heart, was pointed out. The prevalent neglect of this part of physical examination deprives many patients of the relief from cardiac distress which a few leeches would promptly give them. Dilatation of the left ventricle is common in children who are out of health; but Dr. Poynton's observations prove that it is very unusual in children who are quite well for the cardiac dulness to extend beyond the nipple line. The frequency of dilatation only proves that its causes are many; probably the child's cardiac muscle is specially susceptible to toxins and poisons circulating in the blood. One of the most injurious causes is rheumatism, now ascertained to be due to diplococci in the muscles and fibrous tissues of the heart itself. The effect upon the child's future is often most disastrous, and the least symptom of rheumatism in a child calls for the most careful daily examination of the heart by palpation and percussion. The cardiac inflammation in rheumatism may be successfully treated by salicylates, freely given, and the external application of an ice bag (preceded by leeches and with precautions against chill). The ventricular dilatation caused by toxæmia may require strychnine, and perhaps digitalis, but the dangerous dilatation which often follows diphtheria is best treated by the free administration of atropine hypodermically.

A vote of thanks to the President for his interesting address was carried with acclamation.

On receiving the report of the election from the scrutineers (Dr. Symes Thompson and Dr. W. H. Blenkinsop), the President declared the result and inducted the new President, Mr. W. Watson Cheyne, into the chair. Mr. Watson Cheyne briefly returned thanks for the honour conferred upon him, and declared the *conversazioni* open.

A lantern demonstration was given by Mr. Frank Crosbie, showing a method of producing photographic transparencies in colour. Mr. Noble Smith exhibited microscopic illustrations of abnormal gait, &c., in various nervous diseases, and a collection of histological and other water colour drawings. Mr. Hubert C. Phillips, F.E.S., exhibited a valuable collection of British lepidoptera, with original water colour drawings from nature. Music was provided by the string band of his Majesty's Royal Horse Guards (Blue), by permission of Colonel Lord Binning.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, JAN. 17TH, 1902, AT THE EVELINA HOSPITAL FOR SICK CHILDREN.

A. H. TUBBY, M.S., in the Chair.

Dr. GEORGE CARPENTER showed a case of paroxysmal hemoglobinuria in a female child, *æt.* 3. An infant sister had been treated at the hospital for congenital syphilis, but the patient showed no signs of that disorder.

Dr. CHARLES MACALISTER (Liverpool) suggested that absorption from the nasal discharge from which the child suffered might be responsible for the condition.

Dr. G. A. SUTHERLAND called attention to the presence of oxalates in the urine of such cases.

Dr. GUTHRIE spoke of two sisters who developed hemoglobinuria, and who were undoubtedly syphilitic.

Dr. GEORGE CARPENTER, in reply, remarked on experiments showing the immediate destructive action of cold on the red blood corpuscles of such cases, when topically applied.

Dr. GEORGE CARPENTER read notes of a case of suprarenal sarcoma in a boy, *æt.* 2½, the organs from which were demonstrated by Dr. Nabarro, who had conducted

the autopsy. The right kidney was invaded secondarily by the new growth, and the left had become hydropnephrotic from pressure on its ureter. The mesenteric and pelvic glands were secondarily invaded, and some glands under the sterno-mastoid subsequently. The case in its clinical aspect was not unlike tuberculous peritonitis, but the injection of tuberculin gave negative results, and confirmed the original opinion.

Mr. TUBBY and Mr. CLEMENT LUCAS drew attention to the hopelessness of surgical interference in the large majority of cases of renal sarcoma.

Dr. CAUTLEY looked upon it as a case of extra-renal sarcoma, with secondary renal attachment, and inquired as to secondary deposits in the skin.

Dr. GEORGE CARPENTER, in reply, said there were no secondary cutaneous deposits. He did not consider it a case for operation, and that opinion was borne out by the post-mortem examination.

Mr. CLEMENT LUCAS showed a case of Traumatic Chorea and Musculo-Spiral Paralysis, complicating a fracture of the upper third of the humerus, in a girl, *æt.* 11. The chorea developed within half-an-hour of the injury, and was not associated with heart disease or a rheumatic history. The musculo-spiral paralysis was believed to be caused by the callus resulting from movement during repair, and it was proposed to cut down on the seat of fracture and relieve the nerve from pressure. Another interesting point in the case was an abnormal growth of hair on the lower third of the arm and dorsal aspect of the forearm corresponding to the skin supplied by the injured nerve.

Dr. FREDERICK TAYLOR asked whether a recent attack of any infectious disorder could be negatived, and whether it was certain that there were no choreic movements prior to the accident. He observed as to the obscurity surrounding the relationship of chorea to the emotions and shock. How did the traumatism operate? Through the central nervous system, the nerve of the limb, or by the production of shock? Mr. Perret, Mr. Jaffrey, and Dr. George Carpenter joined the discussion, and Mr. CLEMENT LUCAS replied.

Mr. TUBBY showed several cases of paralytic talipes calcaneo-valgus, equino-valgus, and equino-varus which had been treated by muscle grafting. In some of the cases, especially those of calcaneo-valgus, the results were good, also in two of the cases of equino-varus. But the equino-valgus cases were not so striking, although the improvement was very considerable. In his remarks on the operative procedures alluded to, Mr. Tubby said that paralytic cases might be divided for purposes of treatment into three classes: those in which a single muscle or a single group of muscles were affected, and these were capable of satisfactory treatment by tenotomy; those in which at least two groups of muscles were paralysed, and these were fit subjects for muscle grafting; and lastly, those severe cases in which all the muscles around a limb were useless, and for these arthrodesis was recommended. After speaking of the limitations of muscle grafting, and indicating its scope and pointing out that as there was a diminution of power applicable to a given joint the best results could not give a perfect result, Mr. Tubby yet thought that muscle grafting was a scientific and practical procedure, for it distributed what voluntary power was left around an articulation, and so it became well-balanced, although too often weak. The indications and methods of operating in arthrodesis were then alluded to and three cases shown. A case of infantile spastic paralysis affecting the upper extremity was brought forward, in which considerable improvement had been obtained by converting the pronator radii teres into a supinator, and by section of the flexor carpi radialis the patient now has the power of voluntary but partial supination of the forearm. The method adopted is fully described in the *British Medical Journal* of Sept. 7th, 1901, and from an experience of six cases Mr. Tubby thought the operation promised well. Mr. Clement Lucas and Dr. Sansom spoke of the value of Mr. Tubby's suggestions, and Mr. TUBBY replied.

Mr. WALTER EDMUNDS and Dr. GEORGE CARPENTER showed a case of Myositis Ossificans in a female, *æt.* 4, one of a family of eight. The disorder had been noticed six months, and recently had rapidly advanced. The

affected muscles were in parts infiltrated, and in others displayed bony plates. There was fusion of two phalanges of the great toes, a condition which had been recognised as occurring in these cases. Microscopical examination of a portion of an infiltrated muscle showed fibro-nuclear tissue alone.

Dr. MILLIGAN read notes on a case of Contracted Granular Kidney in a boy, *æt.* 7. The chief symptoms were pallor, wasting, headache, and polyuria. The heart was slightly hypertrophied, the skin bronzed, and the urine of low specific gravity and albuminous. Later he developed albuminuric retinitis, and epistaxis and cutaneous hæmorrhages occurred. Four weeks before death the heart began to fail, the extremities became dropsical, giving place to general anasarca, with anuria, and the child died comatose. The kidneys, macroscopically and microscopically, were typical of the condition.

Dr. GEORGE CARPENTER inquired as to a history of syphilis in the case, and said that he had not yet detected albuminuric retinitis in cases of contracted granular kidney in children; but he had seen that condition in a child, *æt.* 8, who suffered from a large white kidney, which was verified post-mortem.

Dr. SANSOM regarded it as one of typical interstitial nephritis, but thought that acute parenchymatous nephritis had been grafted on it.

Dr. SYDNEY STEPHENSON thought it quite possible that retinitis might be as common in interstitial nephritis in children as it was relatively in that disorder in adults. His own experience had furnished him with two such instances, the latter of them two days since.

Mr. SYDNEY STEPHENSON read for Dr. LEWIS MARSHALL (Nottingham), notes on a case of Thyroid Dislocation of the Hip, in a child, *æt.* 9, of four months' duration, confirmed by X-rays. There were two points worthy of note: a previous synovitis of the hip-joint had existed, and reduction was quite easily effected by manipulation.

The meeting then terminated.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, JANUARY 16TH, 1902.

RUSHTON PARKER, B.S., F.E.C.S., President, in the Chair.

FLAGELLATE ORGANISMS IN HUMAN BLOOD.—Major R. ROSS stated that Dr. Dutton, of the Liverpool School of Tropical Medicine, had just found trypanosomes in human blood. Dr. Laveran had previously written asking for details of a case in a lady, reported to the institution by Dr. Barron, in 1895, of "flagellated protozoa in the blood." Further details of this case would be welcome if any member then present could supply them.

Dr. BRIGGS said the patient in question had no fever, and in his opinion Dr. Barron's organisms did not resemble Dr. Dutton's specimens.

HYSTERIC PARALYSIS OF ALL THE EYE MUSCLES EXCEPT THE INTERNAL RECTI.—Mr. EDGAR STEVENSON showed a girl, *æt.* 15, with almost complete palsy of the external ocular muscles. There was marked convergence of the eyes on any attempt to raise the head or to move the eyes. Considerable improvement had resulted from four applications of a high frequency current, the patient now having binocular distant vision.

EXTREME EXOPHTHALMOS IN EXOPHTHALMIC GOITRE.—Mr. STEVENSON also showed a girl, *æt.* 25, from whom the right lobe of the thyroid gland had been removed four years ago. The general symptoms had improved greatly, but the exophthalmos had steadily increased to quite an unusual degree. The cornea were unaffected, and her vision normal.

Mr. SHEARS said excision of part of the thyroid gland had produced no improvement in the exophthalmos, and asked what the present position of thyroidectomy in these cases was. It was remarkable that vision and the mobility of the eyeballs were normal, for the stretching of the optic nerve and external muscles must be extreme.

Mr. R. J. HAMILTON noted the perfect closure of the

lids in this case, and drew attention to the unsatisfactory results of operative treatment for goitre, when marked exophthalmos is present.

Dr. CARTER narrated a case of Graves' disease in a young gentleman, in which cure resulted, he believed, from the exhibition of diluted hydrofluoric and hydriodic acids. Dr. Carter also mentioned two cases in which partial thyroidectomy was performed; in one death followed in a few days, in the other four years after the operation the symptoms were apparently unchanged.

Dr. LOGAN had seen a case of Graves' disease practically cured by a prolonged course of potassium bromide and arsenic. He had seen two marked cases in one family.

Dr. HILL ABRAM said he had seen marked improvement follow partial thyroidectomy, and in Mr. Stevenson's case the general symptoms were notably less than at the time the patient was under observation at the infirmary. Certainly in no other way did we get such speedy relief from the most dangerous symptoms.

MALARIA ACQUIRED IN ENGLAND.—Dr. BUCHANAN described a case with recurrent attacks of fever, in which there was no leucocytosis, and in which one or two of the red cells contained a non-pigmented hæmatozoon. The patient had never been out of England, but had been freely bitten by mosquitoes in Kent.

Major ROSS thought the diagnosis of malaria correct.

Dr. CARTER said a former house physician, the late Dr. Henry Welch, had typical ague in 1880 after a few weeks' residence near Lancaster in early autumn, just after the valley of the Lune had been flooded.

Dr. BUCHANAN replied.

THE UTERINE CURETTE AND CURETTAGE IN GYNÆCOLOGICAL AND OBSTETRICAL SURGERY.

Dr. BRIGGS said that his paper was mainly founded on a consideration of the question, Is the modern estimate of the value of the curette, as shown by its frequent use, amply justified by known results? The results thereof were classified as (1) curative, (2) modifying, (3) exploratory. After reviewing the tests applied to these results Dr. Briggs said the most satisfactory effects of curettage were obtained in the treatment of the uterus, some time after abortion, by the removal of small pieces of chorion; subsequent microscopical investigation for detection of villi should be systematically carried out, otherwise many such cases were described as cures of endometritis. The best use of the curette was indicated by its inventor, Recamier, in 1850; much of the recent practice of curettage belongs to its abuse, which has run parallel with its increased safety. The dull-curette of Gaillard Thomas was advocated by its inventor in the treatment of uterine "fungosities," an "omnibus" title, or most affections of the endometrium known about the mid-period in the history of the curette. Since Nélaton, in 1853, followed by Savage, Routh, Olshausen, Bischoff, Matthews Duncan, and Herman (1880) has described cases of chronic hyperplasia, diffuse or polypoid, of the endometrium, many attempts have been made to differentiate glandular, interstitial, and mixed types of endometritis (Hunter Robb, 1896). Who can, even to-day, separate clinically endometritis, adenoma, and adenocarcinoma at a period when treatment or diagnosis by the curette is most important? The results of curettage in this particular are discouraging. Dr. Briggs thought the estimate of the results of curettage, modifying or exploratory, depended on the whole, more upon dilatation of the cervix to digital size and the use of the finger than upon the mere and otherwise imperfect scraping of the uterus by the curette. A description of the metal dilators used at the Hospital for Women, Liverpool, since 1888 was given; each dilator was made over four sizes of the English catheter scale in the first one and a-half inches from the point. Dr. Briggs then discussed the results obtained in the treatment of metrorrhagia, and showed sections of the endometrium from cases in which a classification might be attempted, but only on incomplete pathological evidence. He alluded to the thickening of the endometrium associated with uterine fibroids, and showed that removal of the fibroid, where justifiable, was the only trustworthy means of arresting the endometrial thickening.

Hence such thickening was probably inflammatory in origin. Dr. Briggs then mentioned several obstinate cases of metrorrhagia, in one, Dr. Murray Cairns, the medical attendant, and the patient, *et. 40*, both pleaded for removal of the uterus, and the operation was eventually carried out. Some of the other cases had had the uterus curetted three times by different doctors, one was apparently cured by turpentine gauze intra-uterine packs. Dr. Briggs maintained that collective investigation after the operation of curettage was required to disseminate doubts as to its present position in minor gynecological, and especially in obstetrical surgery.

Dr. MACPHE CAMPBELL generally used the loop curette, or Donald's flushing instrument. Preferably he curetted first, and then washed out, *débris* were removed with antiseptic gauze, and the uterus packed with the same. His best results were in removal of placental remains in abortion cases; in cases of metrorrhagia he had often been disappointed.

Dr. JOHN E. GEMMELL regarded the finger as the best curette for diagnostic and obstetric purposes, preceded by dilatation of the cervix. He considered, however, that the curette had its place when used intelligently, it was important to carefully weigh the evidence for the true causation of the local condition. Microscopical examination of the tissue removed was most important, especially when considered in conjunction with the feeling imparted to the curette during the operation.

Mr. HAWKINS-AMBLEE said endometritis was a sufficiently defined condition, and the obstacles in the way of cure after curettage lay in the tendency of doctors and patients to look upon the operation as the end, rather than the beginning of treatment. He felt that the finger, although the best curette in post-abortion cases, was not always effectual except in very early cases. The differential diagnosis between adenoma and adenocarcinoma was not possible in many cases from the examination of mere curettings.

Drs. Davie, A. C. Wilson, and Stookes also spoke, and Dr. BRIGGS replied.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, January 25th, 1902.

PROPHYLAXY OF TUBERCULOSIS.

PROF. ROBIN spoke at the Académie de Médecine on the prophylaxy and therapeutics of tuberculosis, based on the knowledge of the seat of that affection. He said that in tuberculous patients from the beginning to the end of the malady the respiratory exchanges were increased. The descendants of those patients showed the same phenomenon, while in those antagonistic pathological conditions of phthisis such as arthritism and scrofula, those exchanges are on the contrary diminished. The exaggeration of the respiratory exchanges was consequently one of the conditions of the lung soil of phthisis. That abnormal activity of the exchanges could be also acquired, as over work (surmenage) and alcoholism exaggerated the respiratory exchanges in the same way as heredity.

Among the consequences of the preceding facts, there were three which deserved to be remarked at once. Since that modification of the respiratory exchanges was almost constant, it could help to make an early diagnosis of phthisis where hesitation between it and another affection would be otherwise justified; it permitted besides to recognise predisposition; it gave a new direction to prophylaxis, since it was only a question of finding what were the medicinal agents capable of restraining the aptitude of the organism of retaining

too much oxygen and of producing too much carbonic acid.

Rest was an excellent sedative of the exchanges as those could be doubled or tripled by sustained energetic efforts. The attitude contributed also to the variation of the respiratory chemical elements; less carbonic acid was exhaled in the reclining than in the sitting posture.

The inspiration of heated and dry air did not act uniformly in all tuberculous patients, consequently before sending one of those patients to a warm and dry climate, it was necessary to examine the chemical elements of his respiration before and after the inspiration of warm and dry air. Such climates would be forbidden to those whose exchanges increased after the experiment. However, it might be said that as a general rule warm and moist climates should not be advised. The inspiration of cold air did not affect the pulmonary capacity nor the quantity of oxygen absorbed by the tissues, but it diminished the amount of carbonic acid produced. Cold climates appeared consequently suitable to the majority of phthisical patients on the condition that the cutaneous surface was not exposed to cold. Among the medicinal agents susceptible of diminishing the respiratory exchanges, the speaker would mention cod-liver oil (ten ounces a day), tartar emetic in fractional doses, arseniate of soda and caseodylate of soda.

DEATH BY CHLOROFORM

was the subject of a general conversation at the meeting of the Société de Chirurgie. M. Poirier related a case of death from syncope due to chloroform in the course of an abdominal operation on a weak old woman. The accident occurred twenty-five minutes after the first inhalation; he incised the diaphragm and the pericardium and seized the heart with his hand, but that organ was flaccid, and no contraction could be provoked.

M. Ferrier said that he had unfortunately to deplore a certain number of deaths from chloroform. But independently of those cases, there existed examples of patients succumbing to fright before the administration of the chloroform. On the other hand, debilitated individuals have succumbed after the first two or three whiffs of the anæsthetic.

M. Quénu thought it would not be strictly right to attribute to fright alone a death occurring at the beginning of the administration of chloroform, for the inhalation of the first whiffs could perfectly provoke in certain predisposed persons the inhibitory reflex which determined the fatal syncope.

For that reason, for the last few years, he has been in the habit of practising an injection of morphia on every one of his patients half an hour before the operation. He considered it an excellent means of preventing cardiac syncope at the commencement of the inhalation of chloroform.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Jan. 25th, 1902.

DISCUSSION ON HR. KAREWSKI'S ADDRESS ON GALL-STONE ILEUS.

HR. GAUS remarked that the large stone shown by

Hr. Karewski had been passed under very extraordinary circumstances. The patient had for years suffered from typical biliary colic, the symptoms of which had gradually become milder after courses of treatment at Carlsbad. During the winter a bad attack returned, with vomiting of blood, and some time after that the stonewas passed at stool. Except from colic, the patient had never been out of sorts. A colleague had been taken ill with violent pain that extended over the whole abdomen, and jaundice then appeared. A diagnosis of biliary colic was made. The patient went to Carlsbad, where, after a temporary improvement, the violent pains returned, and faecal vomiting came on. At the operation an intussusception half a metre in length was found.

Hr. Albu said that Karewski had remarked on the variability of the symptoms, especially as regarded localisation. But one special form had not been mentioned, in which an almost constant symptom of ileus was absent—viz., faeculent hæmorrhage—this form was that of duodenal impaction. He saw such a case some time ago. It was that of a gentleman of 70, who had previously had attacks of jaundice with slight pain, a condition which was supposed to be catarrhal icterus. Then the jaundice suddenly returned, with high fever and small pulse and collapse. The abdomen was distended. No stool or flatus had been passed, but there was vomiting, which, however, was not faeculent. Death took place two days later. On account of the patient's age operation was not thought advisable. Although no autopsy was made, it was plain that the case was one of gall-stone impaction.

Hr. Becher related a case. A lady of 72 had jaundice after an attack of influenza. In September, 1892, after profuse diarrhoea she felt ill, and after a week obstruction occurred with pain under the right ribs. A week later symptoms of ileus came on, although one pultaceous stool was passed afterwards. The cause of the attack was not clear, but laparotomy was performed, and the opening in the abdominal wall came, fortunately, directly upon the obstruction—a calculus the size of a walnut. The patient died in twenty-four hours of collapse. The rupture of the gall-stone into the intestine—and such, from the size of the stone, must have taken place—caused but few symptoms, not more than were usually caused by the breaking through of peritoneal exudation into the rectum or bladder.

Hr. A. Fraenkel would draw attention to the occurrence of cases where the peculiar symptom is observed that faint vomiting is present without stenosis of intestine. He had seen such a case, and he interpreted the symptoms as a communication between the stomach and colon resulting from malignant disease. It was the case of an elderly lady who was suddenly attacked with faecal vomiting, but without distension of the abdomen. The cause was the bursting through of a gall-stone from the gall-bladder into the duodenum. The vomiting was set up by the passage of the decomposing contents of the stomach into the gall-bladder.

Hr. Karewski remarked that it was characteristic for many cases that, in spite of the passage of stools and flatus, ileus was still present. Faecal vomiting without meteorism and with stools almost always was due to gall-stone ileus. Cases such as that related by Fraenkel were very rare. Almost always there was contraction

of the abdomen, as gas and faeces passed, but no fresh chyme passed into the small intestines. Meteorism occurred either from peritonitis from the intestine outwards or from outflow of bile after perforation of the gall-bladder; that was, perhaps, the case in Albu's patient. In one case, that of a man who had suffered from colic for years, it had been assumed that it was a case of ileus due to strangulated hernia. The speaker could not satisfy himself as to the strangulation, but inclined to perforation of the gall-bladder. As the case got worse an operation was performed, when no strangulated hernia was found, but bile in the sac of the rupture. Sometimes intussusception was found in place of the expected gall-stone impaction. Either could cause bleeding. In every case of ileus that had set up no symptoms gall-stones should be borne in mind; a correct diagnosis would then be reached more frequently, and the patient would be more frequently saved by timely operation.

The *Deutsch Med. Zeitung*, 4/1902, contains a reference to a paper by Dr. F. Jarowski on

THE TREATMENT OF GALL-STONE COLIC BY SMALL REPEATED DOSES OF IODIDE OF POTASSIUM.

The writer's experience embraces thirty cases occurring during the past five years. The drug was given in a 2 or 3 per cent. solution, of which two tablespoonfuls formed a dose. The attacks of colic under this treatment soon became less frequent and less painful, tenderness over the right hypochondrium diminished, and after two to three doses the patient gradually got well. The iodide was given in cases after a sharp, short attack of pain; a dull pain was left in the region of the gall-bladder, with great tenderness on pressure. In all such cases no narcotics were given, only the iodide of potassium. As regards the *modus operandi* of the drug, whether it dissolves the stone or only acts as an antispasmodic, the writer says it is difficult to say. In very violent attacks of pain, however, some narcotic is made use of.

The same journal has a reference to a paper by O. Ehrhardt on

ABSORPTION AND TOXICITY OF BILE IN THE PERITONEUM.

A number of experiments were made on animals, and these pointed to the view that in gall-stone peritonitis the inflammation was bacterial. He is of opinion that in the presence of injury treatment must be more active than is the case at present. Most of the cases that were allowed to die from intervention might have been saved by operation. In some cases the gall-bladder would only require suturing. Those cases healed spontaneously in which bland infection set up adhesive inflammation. Operation soon after the injury offers the best chances. In delayed operation it was often impossible to find the wound, so that nothing more could be done than evacuate the bile present. Resorption of bile must be avoided in all cases. If the wound of the bile passage cannot be sutured the bile must be brought outside. The dangers from loss of bile are not so great as those from absorption, and they can, moreover, be overcome by other means. Drainage right up to the seat of injury materially assists recovery.

THE second reading of the "Bill to Secure the Better Training of Midwives and to Regulate their Practice" is down for Wednesday, the 26th prox.

The Operating Theatres.

CHELSEA HOSPITAL FOR WOMEN.

HYSTERECTOMY FOR AN IMPACTED MYOMA OF THE UTERUS.—Dr. ARTHUR GILES operated on a woman, *et. 45*, who had been admitted into the hospital suffering from a tumour that occupied the whole pelvis. Menstruation was regular, but excessive in quantity; she complained of great pain in the pelvis, and of difficulty with micturition. On admission the temperature was high, and the patient looked ill. Examination of the urine showed that it was acid, and contained a large quantity of pus; there was no tenderness in the loins, nor any other symptom pointing to renal disease, and the origin of the pus could not be ascertained. It was decided to wait before operating in the hope of an improvement in the patient's general condition; after a week the temperature was lower, although still above normal, and the amount of pus in the urine had diminished. The woman was allowed to remain for a week further, by which time the temperature had been normal for some days, and the pus had nearly disappeared. The diagnosis was a matter of considerable difficulty, the febrile condition on admission, taken in conjunction with the passage of large quantities of pus, suggested the possibility of an inflammatory condition of the appendages with perhaps a fistulous communication with the bladder or ureter. The hardness of the tumour, on the other hand, was suggestive of myoma; the fact of menorrhagia was consistent with either view. In either case a somewhat formidable operation was anticipated, as it was supposed that many adhesions would be present involving perhaps both the bladder and intestines, but as it was clear that no great improvement could take place without surgical intervention, abdominal section was decided upon. On opening the abdomen the operator was greeted with a pleasant surprise, for the mass proved to be a large myomatous uterus impacted in the pelvis with a small ovarian cyst on the right side; the mass could be lifted out of the pelvis without any difficulty, and no adhesions were present. The myomatous uterus was removed by the usual method of supra-vaginal hysterectomy, which presented no special difficulties. The ovarian cyst on the right side was also removed; whilst the appendages of the left side were allowed to remain behind. The abdominal wound was closed in three layers, without drainage. Dr. Giles said that the main interest of the case lay in the question of diagnosis, for the symptoms, the temperature, pain and menorrhagia, combined with the physical signs of a hard apparently fixed mass filling up the pelvis, and pus in the urine formed an almost complete picture of extensive suppurative disease of the adnexa. No source for the pus in the urine could be discovered either at the time of operation or beforehand, and the most likely explanation before the operation was begun was that a pelvic abscess had communicated with some part of the urinary tract; in the absence of any pelvic suppuration he could only suppose that the pressure of the tumour on the base of the bladder or ureters had been sufficient to cause a certain degree of hydronephrosis with pyonephrosis following. With regard to the forecast of adhesions, it was, he remarked, generally safe to predict trouble from this

cause when a pelvic tumour was accompanied by tenderness and temperature; in this case the tenderness was due to impaction and the temperature to the pyuria. There was no doubt, he said, that if the condition found had been as anticipated the operation would have been a very anxious as well as a very grave one. As things turned out, everything pointed to a favourable issue.

It is satisfactory to state that the patient made an excellent recovery, and left the hospital eighteen days after operation. The pus disappeared completely from the urine a few days after the operation, lending colour to Dr. Giles' supposition as to its origin.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, JANUARY 29, 1902.

MISS COBBE AND THE CURE OF CANCER.

THE recent newspaper discussion upon cancer has brought from Miss Frances Power Cobbe a communication that deserves some passing attention at the hands of the medical profession. It is not that the lady in question is able to throw any fresh light on a disease that has for many centuries eluded the earnest vigilance of medical science, but rather that her attitude may be taken to represent the views of a fairly intelligent, even if hopelessly prejudiced, member of the laity. The letter of January 19th, addressed to the *Daily News* and other journals, reveals a depth of ignorance of the problems and facts of disease, and a placid assumption of all the virtues and attributes of authority that would be ludicrous were it not that the doctrine thus laid down is calculated to do unspeakable harm to human progress. Miss Cobbe paints in glowing colours the terrors of cancer, but while acknowledging the relentless strength and cruelty of the enemy, she nevertheless condemns unsparingly modern scientific methods of investigation and advocates research by what she terms "lawful and humane methods." The argument hinges upon the definition of "lawful" and "humane," as used in her proposition. Let us say there is a ward full of cancer patients: is it more lawful and

humane to practise surgical operations and other methods that offer any chance of relief than to leave those sufferers to die while supplying them with every surrounding that can soften the pain of their passing away? Or, again, turning to the field of comparative experimentation, which is the bugbear ever uppermost in Miss Cobbe's humanitarian flights, would it be justifiable to sacrifice ten thousand guinea-pigs, rats, white mice, and so on, if a single human life might be thereby saved? For our own part we emphatically prefer the interests of the man to those of the lower animals. Miss Cobbe would presumably raise no objection to the slaughter of fish and fowl to feed the cancer patients, and, for that matter, their healthy brethren also. If herrings, and rabbits, and geese, and sheep, and calves, and oxen may be killed, often under circumstances of unspeakable barbarity, for mere sustenance, why should not lives of similar relative standing in the scale of creation be sacrificed for the necessary purposes of the protection and safeguarding of man? Where does the line of lawfulness stop? Is man entitled to exercise absolute control over the bodies and the lives of the lower animals for the purposes of sport, vanity, convenience, commerce, clothing, sustenance, and amusement, but to stay his hand absolutely when it is proposed to extend the assumed right in that direction to the study of the problems of disease? Miss Cobbe says he is not so entitled, and it may be instructive to examine briefly her intellectual methods in advancing that conclusion. First of all, she unreservedly accepts as an established fact the enormous increase of cancer as shown by the returns of the Registrar-General, apparently regardless of the fallacies that underlie any such statistics. The generally accepted view among medical men is that the increase is more apparent than real, and is due to more accurate modern diagnosis and certification. Any scientific writer adopting the view of increase unreservedly in a serious publication would at once be laughed out of court by competent critics as a loose reasoner. The assumption, however, is good enough for Miss Cobbe, and may be taken as a fair example of the critical care bestowed upon the foundations of her position. Her next step is no less fallacious—namely, that it is a "terrific paradox," this increase of mortality "during years in which the habits of the community (and especially those of women) have grown constantly more healthy." That view involves the minor assumption that cancer is closely related to the "habits of the community." So far as we know, there is no evidence in support of any such conclusion. The fact is that medical science is still in ignorance of the ultimate causes of cancer, although the field of observation has been gradually narrowed down so as to make it hopeful that we are within reasonable distance of the discovery of the specific cause of the malady. The greatest advance yet made in the curative treatment of cancer has been the wide removal of the invaded area, together

with neighbouring lymphatic vessels and glands. That advance has greatly increased the chances of successful operation, and is directly due to the knowledge gained by the experimental implantation of cancer in lower animals. The single fact, thus briefly stated, to our mind warrants the whole system of experimental research practised in this country. Experiments on human beings such as those quoted by Miss Cobbe are not performed by medical men in the United Kingdom, unless we except a small number—not mentioned by Miss Cobbe—who do not hesitate to perform dangerous experiments upon their own bodies in their desire to promote the best interests of humanity. As "lawful and humane" methods, Miss Cobbe advocates the use of the Röntgen rays, which have been shown to cure certain superficial forms of cancer in the early stage, but do not touch the deeper and more malignant forms of the disease. She also advocates the light cure and—ye gods!—an infusion of violet leaves. Miss Cobbe, it appears, would infinitely prefer to the sober researches of modern medicine the foregoing and "many another plan which the electrician, the galvanist, the chemist, and the herbalist can suggest." We fervently pity any friends of Miss Cobbe who may trust to such persons in preference to the candour and skill of a good modern surgeon. Miss Cobbe affords a striking instance of a kindly and sentimental enthusiast whose undoubted abilities lack the discipline of that logical training without which kindness and enthusiasm are apt to become misleading forces in intellectual activity.

TOXIC ANALGESICS.

MANY of the somewhat recently introduced synthetic therapeutic agents have proved of the highest value. In affording relief from neuralgia and allied sensory disturbances they have come as a veritable boon, and in these cases have in a large measure replaced opium and its alkaloids; this was a consummation devoutly to be wished, but unfortunately the substitute occasionally proves a treacherous friend. The mania for cocaine, anti-pyrine, and similar drugs is becoming general, with probably a much wider scope than ever the opium habit obtained in these islands. The public obtain access in the easiest way to these newer preparations, thanks to the ingenuity of the modern pharmacist and the laxity of a Government which is proud of its legislation for the preservation of the public health and conscience. Cases of chronic poisoning by these drugs are vastly more common than is generally supposed. In many cases the victims of the habit are probably unaware of or indifferent to the almost incurable conditions they are inducing. It is within the power of medical men to protect their patients to a great extent against contracting the opium and morphia habits, but not so can they calculate on checking the supply of these newer drugs to a patient who has become, or is in danger of becoming, a slave to their use. Legislation is very unlikely to be undertaken against the free

unhindered sale of drugs, which so seldom cause immediate death, and the public can scarcely be expected to understand the toxic nature of the remedies they can so easily obtain once they have learned, with varying difficulty, how to pronounce their names. The unsophisticated public believe the dose recommended on the bottle represents the limits of safety, allowance being made for state of health, age, &c., but there is a fast growing section who are learning to despise these limitations, and who boldly preach to fellow-sufferers, or prospective sufferers, that what is worth doing at all is worth doing well, and so the dosage is increased indefinitely. The occasional report of a case of fatal acute poisoning is one of the things which will make a tyro pause and think; for the *habitué* there is little chance. A case of acute poisoning by sixty grains of acetanilid ending fatally in eight days is reported by Dr. P. King Brown in the *American Journal of Medical Sciences* for December. The principal and most striking features of the clinical symptoms were general hyperæsthesia and not, as one might anticipate, anæsthesia; the reflexes were increased, motor and sensory functions were retained almost to the end. Vomiting was frequent and severe, the arterial pressure was low, the pulse rate steadily increased, the rectal temperature was at first raised but subsequently fell to below normal, a progressive destruction of red-blood corpuscles down to 1,116,000 was noted with a marked increase in the proportion of leucocytes, together with many nucleated red cells, associated with hæmatoporphyria, followed by suppression of urine, mælena, and jaundice.

Notes on Current Topics.

Henoch's Disease.

HAPPILY for us Henoch's disease is almost unknown in the United Kingdom, the disease is, however, not so unusual in the United States, and Dr. Richardson has recently placed an interesting case on record. The case was marked by the suddenness of its onset, commencing without prodromata. The child, eleven years of age was, when apparently in good health, seized with vomiting of blood, pains in the belly and hands, and passed three or four bloody stools. The next day the child was sore from its head to its feet, it was greatly prostrated, and its thighs were covered with purpuric blotches. In a few days all the symptoms disappeared. This favourable result does not always come about. Henoch specially warned his class against giving too favourable a prognosis in such cases, he having more than once met with fatal results. Unfortunately, we know very little of these morbid changes and since 1882, when Henoch and Litton studied them, microscopists have contributed but little to our knowledge. To account for the hæmorrhages a greater permeability of the arterioles than normal is supposed to exist and endarthritic changes such as Koyerer describes have been found in fatal cases. It is withal difficult to believe that marked

structural changes are constant in a disease which begins so suddenly and disappears so quickly. There must be several different conditions grouped together under the common name of purpura, which have nothing in common except the hæmorrhagic symptoms. Henoch leaned to the opinion that the lighter forms were due to a vasomotor neurosis, leading to paralytic dilatation of the smallest vessels, producing stasis of the blood and rupture of the vascular walls or diapedesis of the blood corpuscles. The disease is essentially one of childhood, and appears to be limited to the period between four and fifteen years of age, the great majority of the cases occurring between eight and twelve years. Both sexes appear to suffer equally. Relapses are not infrequent, especially if the child is allowed to rise from bed too soon. There is no specific treatment. Rest in bed, easily digestible foods, and opium are the principal remedies. A case of the disease was reported by Dr. Sutherland in 1897, which shows that we are not wholly immune from it, and this, taken in connection with the case given above, warrants our commenting on the disease, which from its nature is well calculated to alarm a child's parents, and from its rarity in this country might perplex the physician as to its true character.

Newspaper Frauds.

It is strange how little some daily and weekly papers care about their character as advisers of the people. The public press is, to a large extent, the public mentor, though in some cases it little deserves that honourable post. Weekly journals of semi-religious character impart valuable (?) medical advice. Daily papers publish paid quack puffs in so intimate juxtaposition to their genuine news that the reader is often unable to distinguish the difference. It has, however, been reserved for a Belfast daily paper to announce to its readers among its "Arrangements for To-day" the doings of a company which not only are well-known to be professed frauds, but which have been so branded in a court of law. In last May, in the Manchester County Court, his Honour Judge Parry awarded a young lady £50 damages against the British Viavi Company on the ground of fraudulent misrepresentation, and he accompanied his award by some very strong remarks as to the character of that Company. Yet, within the past month, the *Belfast News Letter* inserts in its "Arrangement for To-day" a "Health Lecture," by these nefarious quacks, cheek by jowl with the announcements of meetings of the Young Men's Christian Societies, theatre announcements, and such-like. What can possibly be urged in defence of such degradation of the Press? Ignorance may be considered a reason, but not an excuse. Can it be that the *Belfast News Letter* seeks to make money by advertisements of this kind, and that the Viavi folk will not give them save they receive editorial assistance? Comment on journalism of this nature has not been confined to the columns of medical journals. *Truth*, that keen-nosed tracker of humbugs, has dealt with

the matter in a sensible paragraph, and to its efforts to keep daily literature free from real or apparent dallying with fraud we should like to join our own, in the hope that the *Belfast News Letter*, among others, may profit.

Anopheles.

MANY medical men at home, whose interest has been aroused during the last few years with reference to malaria and the part played by the anopheles in its transmission, find considerable difficulty in following many of the points raised regarding the different species of anopheles. Captain W. G. Liston, I.M.S., has communicated a further article to the *Indian Medical Gazette* for December, in which he describes three more Indian species—the *Anopheles Stephensii*, *Jamesii*, and *Turkhudi*. Appended to careful descriptions are four beautiful drawings, one of these being a descriptive diagram which will doubtless prove of the greatest assistance to those who are in a position and anxious to examine and report on the anopheles found in their neighbourhood. Captain Liston points out that "it is very possible that the cantonment of Ellickpur could be almost completely rid of malarial fevers in a year or so if precautions were taken to rid the place of anopheles mosquitoes," and then proceeds to describe the methods by which he believes this might be done. These principally consist in the sweeping out of small ponds, and treating larger ones with crude paraffin or tar oil once a week. It is pointed out that 50 per cent. of the total admissions to the Jail Hospital and 41 per cent. to the military hospitals during one year were malaria. Captain Liston points out that not only do anopheles make choice of colours, but even more so of materials; for instance, they are rarely taken on linen or silk articles, while they like to rest on woollen materials, furs, or skins.

The Small-pox in London.

THE small-pox, which has shown a slight fall in London, continues to spread in the neighbouring counties. Thirteen cases have occurred in the Gillingham district, and a death at Rochester, both near Chatham, where vaccination is being performed wholesale upon the military and civilian population. A number of cases have occurred in Sittingbourne, another Kentish town, to say nothing of the appearance of the disease at Maidstone and at Canterbury. During the past week Westminster has made chicken-pox a notifiable disease, and has thereby added a most important area to the eight boroughs that have already adopted that important step in prevention. There can be no doubt that the confusion in diagnosis between chicken-pox and small-pox has led to many disastrous errors during the present epidemic. It is somewhat amusing to learn that the Board of Guardians of Whitechapel, which is a notorious anti-vaccinationist centre, have paid over £600 for vaccinations during the past thirteen weeks. The statement has been freely circulated that the outbreak has cost the ratepayers £400,000, but those figures

simply represent the outlay on additional hospital accommodation, and do not take into consideration the cost of maintenance of patients and the economic loss in sickness and death. The London County Council have indignantly repudiated the charge that they have not exercised proper control over the lodging-houses and other dwellings under their control. Dr. Cooper, Chairman of the Public Health Committee, complained that the Government had taken away from the Council its position as the central health authority, and had split the responsibility up among a number of boroughs. In spite of the recent slight decrease in the notifications, the totals show an increase. The hospital admissions for the fortnight ended January 23rd were 447; the number remaining under treatment was 878, being an increase of thirty-five compared with the previous fortnight. On Saturday night the cases under treatment were 900. The total number of admissions from August 10th to January 23rd was 2,353.

Antidiphtheritic Serum and Vaccine Disasters.

No greater misfortune can possibly overtake the public than that its faith in vaccination as a safe prophylactic measure against small-pox should be shaken. It is true that the anti-vaccinationists have been much in evidence, and the conscientious objector has attained to a great degree of notoriety, but the probability is that the latter at any rate is fairly well satisfied with this gain and his public demonstration of his conscience, and has as a rule followed it up by soliciting a more or less private performance of vaccination. The medical profession could justly point with pride to the long record of years of vaccination practice. That it is possible to do harm unless constant carefulness is exercised has been admitted; all the more credit then to the legions of doctors to whose conscientious care it was due that nothing like a public scandal arose while the selection of the sources from which the "lymph" was taken was in their hands. As soon as calf-lymph became compulsory in some places, and insisted on by the public themselves in others, it was well nigh impossible to prevent its becoming an article of more or less ordinary commerce. It might have been supposed that where the preparation of such material as vaccine and antitoxin was undertaken under the direct supervision of public health authorities, none of the dangers were possible which are certain to be present when the material is the subject of commercial competition. We are apt to forget that the introduction of antidiphtheritic serum dates but a very few years back, and that it must be considered to be still more or less on its trial. Can anything be more unfortunate than that it should have thus early to contend against such catastrophes following its use as have lately occurred? Dr. Dalton certainly does not mince matters in an article in the *Canadian Journal of Medicine and Surgery*, for January.

In criticising the methods of the laboratory of the St. Louis Board of Health, he says: "The whole system on which the Board has been in the habit of producing antitoxin seems to have been grossly reckless and in all respects bad." The writer closes the article with the pregnant sentence, "To be impartial, Boards of Health must get out of business," and indeed, if they cannot conduct manufacturing business better than he has represented them as doing, most people will agree with his remark.

Unprotected Firegrates.

THE huge infantile death-rate in modern civilised communities constitutes a standing reproach to the science of preventive medicine. There is little reason to doubt that for the greater part it is due to preventible causes, some of which lie upon the surface, while others are necessarily obscure in our present stage of knowledge. The Home Secretary, Mr. Ritchie, has lately performed a useful public service by emphasising the danger of unprotected firegrates as regards young children. Acting upon a suggestion from the coroner for the City of Nottingham he communicated upon the subject with 200 coroners in England and Wales. The figures obtained in response to his inquiry furnish an appalling proof of the magnitude of this entirely preventible cause of infantile mortality. It appears from this return, a copy of which has been forwarded to the London County Council, as well as to local authorities throughout the country, that in the years 1899 and 1900, the coroners in question held 1,684 inquests on the bodies of children whose deaths had resulted from burning, and that in 1,425 of these cases the evidence showed that the fire by which the burning was caused, had been unprotected by a guard. The official communication from Mr. Ritchie to the County Council, concludes with the following weighty observation. "The loss of life thus brought about is so serious and deplorable, that the facts should be made as widely known as possible, by printed notice to the public or through the local press, and the Secretary of State suggests that steps for the purpose should be taken without delay." By thus calling attention to a public evil, Mr. Ritchie has, to some extent, illustrated the barren wilderness into which his government has wandered, so far as useful preventive measures are concerned.

The Supervision of Restaurant Kitchens.

THE London County Council has somewhat late in the day realised the necessity of exercising a sanitary supervision over the restaurant kitchens of the metropolis. This subject was brought up some years ago by Dr. Waldo, the then Medical Officer of Health for St. George's, Southwark, who published some remarkable facts connected with kitchens attached to restaurants and hotels and also with underground bakehouses. In the latter case legislation has been obtained, and it is sincerely to be hoped in the interests of the community that some stringent regulations will be established in the former as in all other places where food is prepared for con-

sumption by the public. There can be little doubt that the environment of restaurant kitchens is often of the most unwholesome kind, and were it not for the sterilising influence exerted by the process of cooking the results might be disastrous on a large scale. The London County Council have resolved as follows:—"That, considering the thousands of persons in London whose business compels them to have the greater part of their food in public restaurants and eating-houses, and in view of the great importance to the public health that such food should be prepared in wholesome and sanitary surroundings, it be referred to the Public Health Committee to consider and report as to the best means to exercise periodical inspections of the kitchens of restaurants and eating-houses on similar lines as bakehouses and factories are inspected." The introducer of the motion mentioned incidentally that he had been informed by a cook that nothing would tempt him to eat a meal in a restaurant, unless he had previously seen the kitchen arrangements. He had also been told by one of the largest dealers of horseflesh in the metropolis that more horseflesh went into restaurants than was sold for cats' meat. These facts, if established, speak loudly for the necessity of systematic sanitary control of all public kitchens.

Police and Suicides.

AN extraordinary state of affairs in the conduct of the police towards a suicide was disclosed last week at an inquest held by Dr. F. J. Waldo, the City Coroner. It appeared that a horse-dealer, aged 62 years, swallowed some hydrochloric acid. He was seen by a medical man, who prescribed for him, and shortly afterwards he was taken in charge by two constables. Instead of being taken off to hospital, he was walked to the police station, where he was charged and then finally conducted to St. Bartholomew's Hospital, at which institution he subsequently died of shock. These leisurely proceedings in a case of acute poisoning by a corrosive agent are of a nature calculated to cast a severe reflection upon the methods of the police in emergencies of the kind. An ordinary citizen would have bundled the unfortunate suicide into a cab and dashed off with him post haste to a hospital, and there is no reason, so far as appears on the surface, why the constables should have done otherwise with their charge in the present instance. The only shadow of an excuse that can be urged on their behalf is the fact that the deceased had been seen by a medical man, who, however, had ordered his immediate removal to hospital. The interval between the arrival of the police and the delivery of this practically dying man at the hospital was an hour and twenty minutes. As the Coroner remarked, if the unfortunate man had been taken straight to hospital his chances of life, although small, would have been increased. The system that can admit of such an unwise exercise of discretion on the part of police constables clearly requires stringent and common-sense revision.

The Scar Area as a Test of the Efficacy of Vaccination.

VACCINATION has one feature in common with beer—viz., that it is impossible to lay down a satisfactory technical definition of either. The Metropolitan Asylums Board statisticians have accustomed us to take the scar area as a guide to the efficacy of previous vaccination. To this practice there are sundry weighty objections. They are weighty because the adoption of an untrustworthy indication of effective vaccination is sure to furnish the anti-vaccination party with an arm to use against us. It may safely be asserted that neither the size nor the depth of the scar has any necessary relationship to the specific nature of the previous inoculation, indeed it is quite possible that extremely well-marked cicatrices are the result of suppuration caused by the intrusion of pyogenic microbes at, or subsequent to, the inoculation. Every vaccinator of experience will confirm the statement that a typical vaccination may run its course, leaving hardly any visible scar, provided that the operation was performed aseptically and remained free from septic disturbance. It is, moreover, highly probable that the intrusion of pyogenic organisms in any quantity mitigates, and may even destroy, the specific action of vaccine lymph, an assumption which would amply suffice to explain the exceptional instances of vaccination or revaccination not protecting against a subsequent attack of small-pox. Perhaps the experts *in re* vaccination will inform us of the results of their observations on this point. Practically there is only one trustworthy test of the efficacy of vaccination, and that is a clinical one, viz., the immunity of the individual against subsequent infection. Incidentally this action may help us to understand why vaccination sometimes renders the subject refractory to subsequent inoculation and sometimes does not.

Trichinosis and Eosinophilia.

THE number of cases of trichinosis which come under notice is rapidly becoming less, nevertheless the interest attaching to the cases which are discovered from time to time is very great. Such disappearing diseases, and they are all too few, present a field for investigation by the newer methods employed in "blood pathology," which is eagerly seized upon by the patient, painstaking devotees of this branch of modern medical science. A case of trichinosis, which presented many points of particular interest is reported by Drs. Da Costa and Dorset in the *American Journal of Medical Science* for December, and occasion is taken to present a concise *résumé* of the subject of trichinosis. Briefly the details of the case are as follows:—A young man, in consequence of a bicycle accident, wounded the calf of the right leg, but the skin remained uninjured. For over two months the calf increased in size, and soreness and cramp-like pain were experienced when walking. The swelling extending an exploratory incision was

determined on, and in consequence of the appearance of the muscle exposed, a piece was removed and found to swarm with embryo trichinæ. It was subsequently elicited that the patient had eaten for some months previously pork on an average four times a week, though never in a raw state. The diagnostic value of eosinophilia is considered at some length, principally in connection with trichinosis. A constant relative increase in the eosinophiles in this disease has been claimed. Osler is quoted as having found quite a pronounced eosinophilia in five cases. In the author's case, however, no such change could be found.

Wanted, a Descriptive Title.

THE British Optical Association, which appears to be a body composed of working and other opticians, are much exercised in their minds how best to describe their specialty without falling foul of the law. A circular has recently been sent to the members asking for suggestions in reference thereto, and the list of "descriptive titles" before us contains many of the elements of humour. Without soaring quite as high as "doctor of refraction" or "graduate in optics," we are invited to consider the appropriateness of "lensman," "lentist," or "octopus" (why octopus?). These in any event savour too much of trade, hence many may prefer "oculogist," "ophthalmometrician," or "opticologist." The three last have a pronounced scientific twang about them; but we have "pincenecologist" and "professor of optics." "Sighter" and "sightest" are vulgar, and the same remark applies to "spectaclist." We are not entitled to record a vote, otherwise we should be tempted to select "surgeons' optician" or "oculists' optician." At a pinch we might even include "consulting optician." Neonomomenclature is evidently a calling which requires special aptitudes, aptitudes which are by no means invariably possessed by those whose *raison d'être* seems to be the enrichment of the medical vocabulary in defiance of the laws of etymology.

A Municipal Laboratory for Dublin.

AT the last monthly meeting of the Dublin Branch of the National Association for the Prevention of Tuberculosis the question of the voluntary notification of consumption was under discussion, and it was stated that the system as tried in Dublin was practically inoperative. The Hon. Sec. was directed to write to the Public Health Committee of the Corporation pointing out this fact, and urging on them the necessity of providing a Municipal Bacteriological Laboratory, where specimens of sputum could be examined and reported on free of charge. It is now a well-recognised fact that without such an examination a certain diagnosis of the early stages of consumption cannot be made, and without such early diagnosis there is little hope of putting any effective check on the ravages of the disease, which, as was stated, causes some 20 per cent. of the mortality in the city. In the case of the upper classes

the difficulty does not exist, as they can and should, under any circumstances bear the expense of such examination; but in the case of those who are dependent for medical care on the Poor-law dispensaries such expense is out of the question, while it would be equally impossible for the Poor-law medical officers to undertake such an examination for them. The case in reality appears very simple, as if the public health and the medical care of the poor demand the existence of such an institution, there is no reason why it should be denied any more than any other medical requisite. The question of expense is the only real difficulty, but it has been pointed out that such a system has been adopted in nearly all the important towns of England and Scotland, and that the financial difficulty has not been found at all so formidable as was expected. We are firmly convinced that if such a method of diagnosis were at the disposal of the Poor-law medical officers of the city a very real benefit would result to the health of the community, and voluntary notification of tuberculous cases would cease to be the dead letter which it has been up to the present. We sincerely trust that the Corporation will see their way to the establishment of such an institution, and thus remove what must be looked on as one of the chief obstacles in the way of stamping out this disease.

The New Medical Officer of the London School Board.

It is announced that the advisory sub-committee for the appointment of a Medical Superintendent for the London School Board have chosen Dr. Kerr. In view of the importance of the matter a brief record of Dr. Kerr's previous experience will be of interest. In 1893 he was chosen medical officer of the School Board of Bradford, and his duties in that post were on several occasions extended, although at the same time he had sufficient time for private practice. During his tenure of office he advised the Board on general sanitary and hygienic matters, on the health and physical capacity of teachers, and on the general mental and bodily condition of pupils, with special regard to diseases of the eye, ear, and throat. Among other things due to his initiative was a special class for children known as "defectives." The experience thus gained among something like 40,000 children must have been considerable. In selecting a "whole time" candidate of this stamp it may be inferred that the London School Board has at length recognised the supreme importance of safeguarding the health of the children committed to its care. Hitherto there has been practically no medical supervision of the health of scholars, except to a limited extent in epidemic invasions. The authority of the local Medical Officer of Health has been excluded, but the massed groups of children in the Board Schools have been placed under the care of no other shepherd. Should the policy of the London Board prove to be favourable to the systematic inspection of the children, it is clear that a staff of subordinate medical officers will be required. The new departure

of the London Board will be watched with interest by public educational bodies throughout the United Kingdom.

Motor Car Surgery.

AUTOMOBILISM, which is fast becoming such a fashionable pastime, is likely to give rise to its special forms of injury and incapacity. The forces which have to be regulated by the driver of a motor car are much more powerful than those which the simple cyclist commands, and the injuries are naturally of corresponding gravity. We need not dwell upon the terrible fractures and contusions which a spill usually entails upon the unhappy occupants of the car for they do not differ, except in degree, from those which might be caused by being thrown out of an apple cart. The accidents to which we would call attention are those which result from the driving arm being suddenly thrown into forced extension by a sudden jerk of the mechanism. Not unfrequently this determines indirect fracture of the lower extremity of the radius, following rupture or detachment of the anterior ligament of the wrist. On other occasions the injury has been of the nature of a direct fracture, at the junction of the middle and lower thirds of the radius, caused by the handle coming into violent contact with the limb. In one case the styloid process of the ulna was also torn away. Evidently the conduct of a motor car demands a firm hand and a cool head, qualities which are not likely to be invariably found associated.

The Supply of Lymph.

WE cannot congratulate the President of the Local Government Board on the tenor of his reply in reference to the penury of Government lymph. All he had to say was that he had ascertained "beyond doubt" that there is an ample supply of glycerinated calf lymph outside the supply of the Government Department. He "believed" that most of it was very efficient, though the Government lymph was "stronger." This reply reveals a very unsatisfactory state of things. In view of the importance of securing an adequate supply of trustworthy vaccine lymph, it would appear to be the duty of the State either to supply it, not necessarily *gratis*, or to control the supply. At present it is open to any pushing tradesman to supply lymph of unknown origin and still more doubtful efficacy. There are weighty reasons for not restricting the production of lymph to one or two institutions, Government or otherwise, but the risks entailed by imperfectly or carelessly prepared vaccine are too grave for it to be properly left entirely to unsupervised private initiative.

THE death is announced of Dr. and Privy Councillor von Ziemssen, who for many years occupied the position of Professor of Pathology and Therapeutics at Erlangen, and more recently at the University of Munich. Dr. von Ziemssen was an indefatigable worker, and his contributions to medical literature were numerous and important. He was seventy-two years of age.

Remuneration versus Coercion.

THE law providing no means of compelling adult slum dwellers to be vaccinated, it has been found necessary to wheedle them into compliance by small payments, varying in amount from an unstated number of coppers to a bright new shilling. At the latter figure they testify to a willingness to be vaccinated every day of the week. Possibly some such means might be tried with advantage in order to overcome the objection of parents to the vaccination of their children. The expense would probably be less than that entailed by coercive proceedings, especially as the latter so often prove abortive.

Professor Virchow.

It is confidently asserted that the condition of Professor Virchow is "relatively satisfactory," and not such as to justify anxiety. The fact remains that the illustrious professor is suffering materially from the effects of his recent accident, and by reason of his advanced age it is hardly possible to resist a feeling of anxiety, especially in view of his waning strength.

DECISION of character is a great thing when properly applied. The Editor of *Vanity Fair* possesses it, and it enables him to declare with confident emphasis that Colonel Le Poer Trench's last letter to the *Times* is "a gentleman's letter." In the Editor's opinion, it is unanswered and therefore irrefutable. He is moved to ire at the spectacle of the gallant Colonel being "contemptuously trampled upon by any apothecary" whose "coarse disregard for common courtesy" is equalled—well, let us say by that of the Editor of *Vanity Fair*, whose inconsequent insolence may tickle the groundlings, his readers, but must make the wise man weep.

It has been decided to appoint a Medical Officer of Health to the Doncaster Rural District Council, at a salary of £300 per annum, with the right to take pupils, give consultations, &c.

PERSONAL.

THE appointment of Dr. Wroughton Gerald Heath, Medical Officer of Montserrat, to the Legislative Council of that Presidency has received the Royal assent.

MR. JAMES KERR, M.A., M.D.Cantab., Medical Officer to the Bradford School Board, has been selected by the Committee of the London School Board, from 148 candidates, to the vacancy caused by the resignation of Dr. W. R. Smith.

MR. PHILIP DE SANTI, F.R.C.S., Senior Assistant Surgeon and Surgeon-in-Charge of the Ear Department at Westminster Hospital, has been appointed Surgeon to the Throat, Nose, and Ear Departments, which have been amalgamated at Westminster, and, in consequence, has resigned the Assistant Surgeoncy.

DR. F. W. PAVY, F.R.S., has been elected President of the Fourteenth International Congress of Medicine, vice Sir William MacCormac, Bart., K.C.B., deceased.

At the meeting of the Committee at which the new President was elected, the secretaries were ordered to transmit to Lady MacCormac an expression of their deep sympathy in her bereavement, and recognition of the great value of the late Sir William MacCormac's services to the various International Congresses with which he had been so closely connected.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

GLASGOW UNIVERSITY AND THE CARNEGIE TRUST.

THE University Court have just issued a statement in response to the Carnegie Trustees' letter asking for the opinions of the Universities as to their requirements so far as they came within the scope of the operations of the Trust. The University asks the Carnegie Trustees for capital grants amounting to £95,000, and for an annual grant of £15,205. With regard to the former of these, the objects for which the money is required are the foundation of a Chair of Geology (£27,500), new laboratories (£75,000), apparatus (£8,000), and the library (£8,500). The Chair of Natural History has, since its foundation, comprehended the two sciences of Zoology and Geology, and it is agreed on all hands that the time has now come for the teaching of the two to be separated. The present occupant of the chair has intimated his intention to resign, and it is most important that the separation should be made before the appointment of a successor. The Court have received a conditional promise of £6,000 from the Bella Houston trustees, and hope that £1,500 may be collected otherwise for this object: they therefore apply to the Carnegie Trust for the balance necessary. The Court points out that they have already done all in their power to meet the great and growing needs for laboratory extension. An arrangement was made in 1894 with the Western Infirmary for the erection of a pathological department there, and the University pays a rental of five per cent. on the cost of building, as well as meeting the expenses of lighting, &c. A new botanical laboratory has been erected at a cost of £16,000, a new engineering laboratory is almost completed, and will cost £40,000, a surgical laboratory is being erected at an estimated cost of about £10,540, and a new anatomical laboratory has been completed at a cost of £13,500. The funds necessary have been supplied by the Bella Houston Trustees, the general university fund, the Randolph fund and the Paterson fund, as well as by the generosity of private subscribers. The two last named funds are now exhausted. To meet the further requirements of the university, there are needed laboratories in natural philosophy, physiology, forensic medicine, materia medica, chemistry and geology. For these it is estimated that £150,000 will be required. It is hoped that a grant of half this sum, conditional on the university finding the other half, will be provided by the trustees. The annual grant of £15,000 asked for is proposed to be devoted to the foundation of a Lectureship on Organic Chemistry, with a salary of £400, and to the payment of a greater number of trained demonstrators in science and medicine. In this connection reference is made to the science school of Cambridge, which, untrammelled by use and want, has largely replaced systematic lecturing by practical work, with the necessary division of students into groups of ten or twenty, each under the direction of a demonstrator. Fully to carry out this system in Glasgow in the various subjects of the medical curriculum would entail an expenditure of £5,000 a year, and there would be a further annual charge of £2,000 for material and apparatus. The Court has already appointed special lecturers on engineering and electrical engineering, and special lecturers on one or more of the subdivisions of natural philosophy, such as chemical physics or physical optics, as well as on vegetable economics and on experimental psychology are greatly required. In the Arts Faculty Lectureships on Political Economy, English

language and English history are needed, while as less urgent requirements Arabic and Italian are mentioned. Research Scholarships on the following subjects, which are enclosed in the scope of the trust deed—viz, natural philosophy, astronomy, engineering, naval architecture, mathematics, botany, chemistry, anatomy, pathology, practice of medicine, surgery, pathology therapeutics, forensic medicine, public health, history, English literature, English language, economics, modern languages, and Arabic—would do much to encourage post-graduate work, and the Court suggests that these, which would cost £2,800, should be filled each year by the Faculty, the number of Fellowships not being fixed, and none being allocated definitely nor in perpetuity to any one of the subjects mentioned. The document here quoted is the first public intimation of the demands of any of the Scotch Universities on the Carnegie Trustees, and if the amount asked for seems large it must at least be conceded that the proposals for its disposal are well thought out. Whether or not the University gets all it asks for, the public will learn that good science teaching means money, and will understand better what our Universities really need to compete with the better equipped institutions of America and Germany.

PROPOSED PSYCHIATRIC CLINIQUE IN EDINBURGH.

This question has been reopened by Sir John Sibbald, and in connection with the movement a meeting was held in the College of Physicians, at which a number of medical teachers, alienists, and those interested in medical education generally were present. Sir John Sibbald read a paper detailing the educational advantages of such a scheme, and pointed to its necessity from a charitable point of view. Those who have studied in Germany cannot have failed to perceive that in the psychiatric clinics of the hospitals certain cases are treated, many of which receive but slight attention in our infirmaries at home, being generally rustled off to the parochial authorities, or after a brief sojourn in the ward reserved for an *olla podrida* of "D.T.'s," poisoning cases, and noisy patients generally, are packed off to an asylum or their homes without being a whit better for the treatment, or lack of treatment, they receive. Any one with experience of outpatient practice must often have racked his brains as to what was best to be done with some poor creature on the "borderland," or a neurasthenic artisan who assuredly requires something more than the course of faradism which he is likely to receive in a general medical ward. From the educational point of view the value of such a clinique would be enormous, and would enable the student to see before he graduates cases which (as matters are at present) too frequently do him little credit when he meets them in private practice later on. It is satisfactory to learn that a committee was appointed to further the matter, and that general discussion of the scheme has been arranged for an early meeting of the Medico-Chirurgical Society.

SMALL-POX.

There are now (25th) forty-nine cases of small-pox in Glasgow, while in the reception house, which is used almost exclusively for suspects and contacts, there are thirty-five inmates. Three cases have developed in a lodging-house in Linlithgow during the week. The Town Council offer free vaccination to all those above seven years in consequence of the outbreak. A case has also occurred in Dundee.

Special Article.

AN OBJECT LESSON IN MEDICAL FRATERNITY?

We have received the following statement, with a request that it may be published, from the hon. secretary of the Midland Medical Union:—

From time to time particulars of a dispute between the Teveral Colliery Club and their surgeon have appeared in the medical journals. In view of recent developments we give the following *résumé*. Early in 1901, Dr. Rainsbury, of Skegby, Notts., who held a colliery appointment to the Teveral Colliery Club, commenced

to charge the fee of 21s. for midwifery cases. This was an increase from 10s. 6d. In consequence Dr. Rainsbury was threatened with dismissal from his appointment. A deputation from the Midland Medical Union waited upon the Club Committee to point out the reasonableness of the fee, and asking them to give the matter careful consideration. However, they sent Dr. Rainsbury an agreement to sign, in which he should bind himself to charge a sum of 10s. 6d. for members' wives attended by him in their confinements. This he refused to do, and in consequence was served with three months' notice.

The Colliery Club then advertised for a surgeon; the Union advertised warning men from accepting the post, and through the courtesy of the editors of the medical papers no more advertisements were inserted from the Colliery Club. The club, however, managed to secure a medical man who agreed to accept the appointment; but from knowledge which came to the Club Committee, a letter was sent to him asking him to come at once, and enclosing him three months' notice; in consequence of this he never came to take up his appointment. The result was that after Dr. Rainsbury's notice expired on June 25th, 1901, the club was without a medical officer, and Dr. Rainsbury continued to attend the men and their families, but at private rates.

In November, 1901, the club secured the services of Dr. Alexander David Crawford, who took Dr. Rainsbury's appointment on condition that he should also be given the appointment of a neighbouring practitioner under the same Club Committee—a practitioner who had been asked to accept Dr. Rainsbury's post and had refused. This practitioner (Dr. Mitchell, of Sutton-in-Ashfield) was forthwith dismissed by the Committee, and Dr. Crawford introduced a partner, Dr. Robert James Sharman, into Sutton-in-Ashfield, to carry on that part of the work.

This step on the part of Dr. Crawford and his partner was taken after the case had been fully explained to them, and after the Midland Medical Union, acting on behalf of the local medical men, had begged Dr. Crawford to have nothing to do with the appointment.

These two medical men are now carrying on the work for these collieries.

The Midland Medical Union wish to place this statement of facts before the profession generally, and ask for expressions of opinion with regard to the action of Drs. Crawford and Farman.

The Council of the Midland Medical Union, at a meeting held in Nottingham on January 17th, 1902, declared Drs. Crawford and Farman to be opposed to the objects and interests of the Union, and by a previous resolution of this Union every member is pledged to abstain from giving such practitioners any professional assistance by consultation or otherwise.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

OPEN-AIR TREATMENT OF CONSUMPTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an interesting little book by Dr. Euata, of Perugia, on "Pulmonary Tuberculosis," we read that in 1830 Dr. George Bodington, of Sutton Coldfield, Warwickshire, established an open-air sanatorium. The doctor published a book in which he insisted much on the patient living in the open-air heedless of wet and even intense cold.

The result appears to have been a failure; Dr. Bodington's treatment was denounced by the doctors of the day, and the sanatorium, after a few years' trial, was made into a lunatic asylum.

It is rather a curious matter for speculation in this present enlightened day how it came about that a method of treatment for consumption so highly extolled in 1900 should have been a failure in 1830-40. The explanation seems to be that in Bodington's day neither the profession nor the public were educated up to this novel and subversive way of dealing with consumption.

Very little was then known of physical diagnosis, and nothing whatever of temperature taking and microscopic examinations of sputum.

Under this state of knowledge, doubtless, cases of inflammatory bronchitis and congestive pneumonia were placed under the open-air treatment with disastrous effect on the patient. We know how one or two conspicuous mishaps will knock down a new method when just in its beginning.

It is interesting now to see in the open-air treatment a practical outcome of work with stethoscope, thermometer, and microscope. The diagnosis of genuine tuberculosis, as marked by the presence of the tubercle bacillus, is assured, while the thermometer shows in what direction the case is tending.

Though experience has taught me how very rarely gout and consumption are met with in the same constitution, I cannot but fear harm will come in some cases from the excessive feeding that goes along with the open-air method. If true gout be thus developed I should have great hope of a recovery, but during the process we must remember that a violent hæmoptysis or an attack of apoplexy and paralysis may overthrow our best hopes.

I am, Sir, yours truly,

JOHN C. THOROWGOOD, M.D., F.R.C.P.
Bognor, January, 1902.

"SUPERFETATION."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Your correspondent "X" is not quite correct in stating that with one accord such works on midwifery as allude to the condition of superfetation say that its occurrence is impossible. Has he never read Tyler Smith's "Manual of Obstetrics," which gives a most interesting case of superfetation? The case was this. A young married woman pregnant for the first time, miscarried at the end of the fifth month, and some hours afterwards a small clot was discharged, enclosing a perfectly healthy ovum of about one month, &c.

Again, I would suggest to "X" to read Dr. Bonnar's (of Cupar) views and proofs contained in the *Edinburgh Medical Journal* (1864-65).

Briefly, my case was this. Mrs. K, mother of five children, was confined on the morning of May 3rd, 1899. Two boys were born, and I, thinking the case, so to speak, was ended, tied the cords and commenced pressure to expel the placenta, when to my surprise a small fetus was born (female).

The males were very nearly full time, but the female was about four months.

The difference between the sizes of the triplets, and the fact of a common placenta between the males, left, and still leaves little doubt on my mind, but that the female was conceived when the uterus had already contained an ovum which had arrived at a considerable degree of development.

I am, Sir, yours truly,

M. C. O'GORMAN, L.R.C.S.I., &c.

POT. IODID IN BRONCHIAL ASTHMA.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It was with great pleasure that I read in your paper of to-day a clinical report which demonstrated the value of full doses of iodide of potassium in certain forms of bronchial asthma.

This chemical at one time enjoyed a great reputation in the therapeutics of asthma and came to form the principal ingredient in the quack remedy, Dr. Aubree's "Asthma Cure" in which it was combined with lactucarium and chloroform. It seems, however, not to have survived Hyde Salter's condemnation in 1860, and although Dr. Neale went out of his way to recommend it in his excellent "Medical Digest," it has remained comparatively unknown in the treatment of this dreadful complaint. The notice of its therapeutic properties in asthma when used as a spray is mentioned by Binger. In his last edition Dr. Hone writes, "The curative treatment of asthma to a large extent rests upon the use of

iodide of potassium." In my own practice I have had the best possible results from its use in bronchial cases.

I am, Sir, yours truly,

MEDICUS.

NEW BOOKS AND NEW EDITIONS.

The following books have been received since the publication of our last monthly list —

BAILLIÈRE, TINDALL AND Co. (London).

The Imperial Health Manual. Authorised English edition of the official German Manual. Second Edition. Edited by Anthony Roche, M.B.C.P., &c. Pp. 318. Price 3s.

Text-Book of Pathological Anatomy, including Post-Mortem Examinations and the Methods of Preserving and Examining Diseased Tissues. Sixth Edition. By Profs. Delafield and Prudden. Pp. 1,012, with coloured plates. Price 21s.

The Estivo-Malarial Fevers. By Charles F. Craig, M.D. Pp. 211, with coloured plates. Price 10s. 6d.

CENTURY PRINTING COMPANY, LIMITED (London).

The War against Consumption. By Dennis Vinrace, M.B.C.S. Revised by J. H. Vinrace, M.B., M.R.C.P.Lond. Pp. 178. Price 2s. 6d.

J. AND A. CHURCHILL (London).

Nursing—General, Medical, and Surgical—with Appendix on Sick-room Cookery. By Wilfred J. Hadley, M.D., F.R.C.P. Pp. 326. Price 3s. 6d.

The Operative Surgery of Malignant Disease. By H. T. Buthin, F.R.C.S., D.C.L. Second Edition. Pp. 436. Price 14s.

CROSBY, LOCKWOOD AND SON (London).

Water and its Purification. By Samuel Rideal, D.Sc.Lond. Second Edition. Revised and Extended, with numerous Illustrations. Pp. 346. Price 9s. net.

OCTAVE DOIN (Paris).

Clinique des Maladies du Système Nerveux, Hospice de la Salpêtrière. Edited by Professeur Raymond. Quatrième Série. Pp. 666. Avec 2 planches col. Prix 15 fr. Also Cinquième série. Pp. 678, avec 5 planches col. Prix 16 fr.

CHARLES GRIFFIN AND Co. (London).

A Handbook of Hygiene. By A. M. Davies, M.B.C.S., Licent. Col. B.A.M.C. Pp. 621. Price 8s. 6d.

Outlines of Practical Physiology. By Prof. Stirling. Fourth Edition. Pp. 624. Price 15s. net.

Practical Sanitary Engineering. By Francis Wood, A.M.Inst.C.E., F.G.S. Pp. 304. Price 8s. 6d. net.

H. K. LEWIS (London).

Bacteriological Diagnosis. By W. D'Este Emery, M.D., B.Sc. Lond. Pp. 231. Price 5s. 6d.

Rough Notes on Remedies. By Wm. Murray, M.D., F.R.C.P. Lond. Pp. 183. Price 4s.

LIPPINCOTT AND Co. (Philadelphia):

An Experimental and Clinical Research into Certain Problems relating to Surgical Operations. By George W. Crile, A.M., M.D. Pp. 300. Price 12s. 6d.

Pediatrics, the Hygiene and Medical Treatment of Children. By T. M. Rotch, M.D., Harvard. Pp. 1,020. Price 25s.

LONGMANS, GREEN AND Co. (London).

Quain's Dictionary of Medicine, by various Authors. Third Edition. Edited by H. Montague Murray, M.D., F.R.C.P., assisted by J. Harrold, M.B., and W. C. Bosanquet, M.D., M.R.C.P. Pp. 1,892. Price 21s. net.

Directions for Class Work in Practical Physiology. By E. S. Schafer, LL.D., F.R.S. Pp. 76. Price 3s. 6d.

YOUNG J. PENTLAND (Edinburgh and London).

The Edinburgh Medical Journal. Edited by G. A. Gibson, M.D., F.R.C.P.Ed. Vol. x New Series. Pp. 600.

REBMAN, LIMITED (London).

The Medical Treatment of Gall-stones. By J. H. Keay, M.A., M.D. Pp. 126. Price 3s.

THE SCIENTIFIC PRESS, LIMITED (London).

Poison Romance and Poison Mysteries. By C. J. S. Thompson, F.R.E.S. Pp. 295. Price 2s. 6d.

SMITH, ELDER AND Co. (London).

The War in South Africa, its Cause and Conduct. By A. Conan Doyle. Pp. 156. Price 6d.

Therapeutics: its Principles and Practice. By Horatio C. Wood, M.D., LL.D. Eleventh Edition, remodelled. Pp. 890. Price 18s.

Artificial Feeding and Food Disorders of Infants. By W. B. Cheadle, M.A., M.D. Fifth Edition. Pp. 268. Price 5s.

Lectures on Chemical Pathology in its Relation to Practical Medicine. By C. A. Hertter, M.D. Pp. 461.

G. STEINHEIL (Paris).

Etudes Anatomiques des Grossesses Tubaires. Par le Dr. A. Couvelaire, Chef de Clinique Obstetricale a la Faculté de Médecine de Paris. Pp. 160, avec 12 planches. Price 10 fr.

WILLIAMS AND NORWORTHY (London).

Studies in Heterogenesis. By H. Charlton Bastian, M.D., F.R.S. Part I. Pp. 76, with plates. Price 4s.

WILLIAM WOOD AND Co. (New York).

A Manual of Clinical Laboratory Methods. By J. B. Nichols, M.D. Illustrated. Pp. 310. Price 2'50 dols. net.

JOHN WRIGHT AND Co. (Bristol).

First Aid to the Injured and Sick. By A. C. Tunstall, M.D., F.R.C.S.Ed. Pp. 232. Price 2s. 6d.

Elementary Bandaging and Surgical Dressing. By the late Walter Pye, F.R.C.S. Revised by Thos. Cawardine, M.S., F.R.C.S.

LITERARY NOTES.—Messrs. Smith, Elder and Co. have published this week a work entitled "Lectures on Chemical Pathology in its Relation to Practical Medicine," by Dr. C. A. Herter, Professor of Pathological Chemistry, University and Bellevue Medical Schools, New York. They will also publish immediately a fifth edition, revised and edited by Dr. F. J. Poynton, of Dr. Cheadle's well-known work on "The Artificial Feeding of Infants."

MESSERS. BAILLIÈRE, TINDALL AND COX have issued during the present week a third edition of "The Röntgen Rays in Medical Work," by Dr. David Walsh, with electrical portion by Dr. Lewis Jones. A new edition of the "Imperial Health Manual"—Officially authorised by the German Government. Translation by Dr. Roche, of Dublin. Also a sixth edition of Professors Delafield and Prudden's well-known text-book of "Pathological Anatomy and Post-Mortem," and a new work on "Malarial Fevers," by Dr. Chas. F. Craig.

At the death of the late Professor Manassein it was learned with considerable surprise and regret by the medical profession in Russia that he had left very explicit directions that the publication of *Vratch*, a journal of which he was the founder and editor, should be discontinued with the closure of the volume current at the time of his death. The journal will, therefore, die with the year, but its place will be taken by a new one called the *Russki Vratch*, or "Russian Physician."

Sanitary Improvements at Windsor Castle.

CONSIDERABLE improvements, amounting to reconstruction, have been made in the sanitary arrangements of the southern part of Windsor Castle, recently occupied for a few days by their Majesties, by the officials of His Majesty's Office of Works, under the advice and supervision of Professor Corfield, their consulting sanitary adviser. The whole of the drains under the south towers, from Edward III.'s Tower to the Victoria Tower, inclusive, have been done away with, so that there is now no drain under the buildings on that side of the castle, and new watertight iron drains have been laid outside the buildings. Internal water-closets and soil-pipes have been cleared away, ventilated loobies formed in connection with the water-closets, new soil-pipes fixed outside the building, and the best improved appliances of all kinds fixed. Suitable disconnection arrangements have been provided between the new drains of the Tower and the Castle sewers, so that each of the Towers is, in fact, so far as the drainage is concerned, a house in itself. Similar improvements, we are informed, will gradually be carried out throughout the rest of the Castle.

The Medical Lodge of Masons.

THE St. Luke's Lodge of Instruction held its first meeting on Monday, the 20th inst., at the Criterion Restaurant. This Lodge of Instruction is the tangible result of the work done by a Committee representing the various medical lodges of the metropolis, which was appointed last session to consider the subject. Bro. Ernest Clarke, W.M., of the Esculapius Lodge, occupied the chair, and was supported by Bros. Duncan and Luff, of the Middlesex Hospital and Sancta Maria Lodges respectively, and some forty influential and representative members of the various medical lodges. The principal business of the evening was the passing of the bye-laws, at the conclusion of which a vote of thanks to Bro. Rowell, the Secretary of the original Committee, upon whom has fallen the brunt of the work in connection with the preliminary organisation of the lodge, was received with acclamation and ordered to be entered on the minutes. Bro. Achard was then appointed Preceptor, and the second degree was rehearsed. The St. Luke's Medical Lodge of Instruction proposes to meet each Monday in the month, from October to May inclusive, with the exception of those falling in the Christmas vacation, Easter Monday, and Whit Monday. The Secretary is Bro. Eyre, of Embankment Chambers, Villiers Street, London, W.C.

Clitheroe Dentists Committed for Manslaughter.

At an inquest held at Clitheroe a verdict of manslaughter was returned against Thomas Crook and James Lancaster, uncertified dentists, practising at Clitheroe and Blackburn. On Tuesday night a young married woman named Hotherhall died at their surgery whilst under chloroform. According to a doctor's evidence the woman died from an overdose of chloroform. The doctor further said that he did not see that the ordinary means of restoration had been applied. Life was extinct when he was called in, and the woman was being held in an upright position instead of a recumbent one. The jury found that death resulted from an overdose of chloroform unskillfully administered, and both were committed to the assizes.

North of England Obstetrical and Gynaecological Society.

THE following is a list of officers elected for the year 1902 at the annual meeting on the 17th inst.:—President: S. Buckley, M.D., Manchester. Vice-Presidents: Arthur T. Helme, M.D., and D. Lloyd Roberts, M.D. (Manchester); J. E. Burton, L.R.C.P., and E. T. Davies, M.D. (Liverpool); T. Kilner Clark, M.D. (Huddersfield); C. J. Wright, M.R.C.S. (Leeds); G. H. West Jones, M.R.C.S., and J. W. Martin, M.D. (Sheffield). Council: R. W. Beesley, M.D. (Bolton); A. Donald, M.D., W. E. Fothergill, M.D., Arnold W. W. Lea, M.D., W. Sawers Scott, M.D., W. Japp Sinclair, M.D., and W. Walter, M.D. (Manchester); W. Murray Cairns, M.B., and J. Garner, M.D. (Preston); T. B. Grimsdale, M.B., and Llewellyn Morgan, M.D. (Liverpool); J. Huskie, M.B. (Blundellsands); E. Thacker King, L.R.C.P. (West Kirby); J. Lambert, M.D. (Birkenhead); F. P. Bouverie McDonald, M.D. (New Brighton); T. C. Denby, M.D. (Bradford); J. B. Hellier, M.D., H. Littlewood, F.R.C.S., and H. Robson, L.R.C.P. (Leeds); C. N. Gwynne, M.D. A. A. Payne, M.R.C.S., and Sinclair White, M.D. (Sheffield). Honorary Treasurer: Richard Favell, M.R.C.S. (Sheffield). Honorary General Secretary: E. Octavius Croft, M.D. (Leeds). Honorary Local Secretaries: John Scott, M.D. (Manchester); Arthur Wallace, M.D. (Liverpool); Walter Thompson, F.R.C.S. (Leeds); Sidney Barber, M.R.C.S. (Sheffield).

British Gynaecological Society.

At the annual meeting held on the 16th inst. the following office-bearers were elected:—Hon. President: Robert Barnes, M.D., F.R.C.P. President: John Halliday Croom, M.D., F.R.S.E., F.R.C.P., F.R.C.S.E. Vice-Presidents: W. Armstrong, M.R.C.S. (Buxton); Prot. Murdoch Cameron, M.D. (Glasgow); John Campbell, M.D., M.A., F.R.C.S. (Belfast); Clement Godson, M.D., M.R.C.P. (London); F. W. N. Haultain, M.D., F.R.C.P. (Edinburgh); Skene Keith, M.B., F.R.C.S. (London); J. A. Mansell Moullin, M.A., M.B.; James Oliver, M.D. (London); John Shaw, M.D., M.R.C.P. (London); Prof. W. Japp Sinclair, M.A., M.D., M.R.C.P. (Manchester); Alfred Smith, M.B., F.R.C.S.I. (Dublin); Heywood Smith, M.D. (London). Treasurer: W. Travers, M.D., F.R.C.S. (London). Council: W. Alexander, M.D., F.R.C.S. (Liverpool); A. H. Barbour, M.A., B.Sc., M.D. (Edinburgh); E. Stanmore Bishop, F.R.C.S. (Manchester); W. H. Bourke, M.D. (London); Eber Chambers, M.D. (London); R. J. Colenso, M.A., M.D. (London); E. T. Davies, M.D., F.R.C.S. (Liverpool); T. M. Dolan, M.D., F.R.C.S. (Halifax); Bedford Fenwick, M.D., M.R.C.P. (London); Hugh Hodgson, M.D. (London); T. Jago, M.R.C.S. (Lond.); J. Jardine, M.B., C.M. (Richmond); H. Jellott, M.D., F.R.C.S. (Dub.); F. Bowreman Jessett, F.R.C.S. (Lond.); H. Macnaughton-Jones, M.D., F.R.C.S.I. (Lond.); F. W. Kidd, M.D., B.A. (Dub.); Inglis Parsons, M.D., M.R.C.P. (London); F. W. Ramsay, M.D. (Bournemouth); F. F. Schacht, M.D., B.A. (London); W. Slimon, M.D., F.F.P.S. (London); W. J. Smyly, M.D., F.R.S.C.I. (Dublin); Herbert Snow, M.D. (London); W. D. Spanton, F.R.C.S. (Hanley); Septimus Sunderland, M.D., M.R.C.P. (London); J. W. Taylor, F.R.C.S. (Birmingham). Editors of the Journal: J. J. Macan, M.D., M.A. (London); H. M. Macnaughton Jones, M.B. (London). Hon. Secretaries: Charles Ryall, F.R.C.S. (London); J. H. Swanton, M.A., M.D. (London). Trustees of the Property of the Society: G. Granville Bantock, M.D., F.R.C.S.; R. S. Fancourt Barnes, M.D., F.R.S.E.; Clement Godson, M.D., M.R.C.P.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A SUBTLE DISTINCTION.

MEDICAL writers are often embarrassed to define with any approach to accuracy the condition of a person suspected of alcoholic inebriety. At a recent trial a witness said: "I don't think that he was what you might call drunk—very drunk—but he was intoxicated, what you might call very badly in liquor." An interesting example of subtle distinctions, it must be admitted.

MISS D. W.—We do not know of any institution which fulfils your requirements at anything like the fees you suggest. The lowest cost would be from six to eight guineas.

M.R.C.P. 1.ond.—As canvassing is not prohibited, and the elective body, the Board of Management, are mainly composed of laymen, it is obvious that any candidate who does not exert himself to obtain votes from members of the Board will find himself handicapped in the competition. Nevertheless, we entirely agree with our correspondent that the system of canvassing the lay governors should be abolished in all cases where hospital appointments are concerned.

HEAD TROUBLES.

"It's my head that's been troubling me so lately, my dear," the old lady remarked to a young friend, "and the doctor he says 'You take these y'ere pills,' says he, 'and you will soon shake it off.'"

DR. HAMILTON's letter is unfortunately crowded out "at press." It will appear in our next.

HOT-WATER BOTTLE SUBSTITUTE.

A simple plan suggested by a writer in the *Philadelphia Medical Journal* is to wrap an ordinary electric-light bulb in flannel and apply to the part. The lamp is attached to an ordinary flexible connection, and when the current is turned on it gives off a steady heat very comforting in painful affections of the chest, abdomen, &c. As long as the lamp is alight the heat is maintained and does not decrease as with a hot-water bottle.

MR. J. A. C.—The subject is not sufficiently interesting to give so much space to its discussion.

QUESTOR.—We think "medical etiquette" has been very much strained in this case, which is one where both sides might give away without loss of dignity. A meeting might be arranged, when a frank explanation should at once remove any vestige of friction.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, JAN. 29th.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20, Hanover Square, W.).—8.30 p.m. DR. I. MURRAY: Note on Hayling Island. Paper:—MR. W. ARMSTRONG: Adjuncts to Spa Treatment.

THURSDAY, JAN. 30th.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11, Chandos Street, Cavendish Square, W.).—Cases and Specimens by Mr. Keeling, Mr. Hickman, Mr. Roll, Mr. Ormond, Mr. Parsons, and Mr. Taylor. Papers:—DR. C. O. HAWTHORNE: On Intra-cranial Thrombosis as the Cause of Double Optic Neuritis in Cases of Chlorosis.—DR. G. A. BERRY: (1) On so-called Muscular Asthenopia; (2) Note on the Treatment of Cystoid Cicatrix following Cataract Extraction.—MR. S. SNELL: (1) Tumour of Orbit occasioning a peculiar Varicosity of Vessels on the Surface of the Eyeball; (2) Ringworm of the Eyelids in an Adult due to a Large-spored Trichophyton.—DR. F. W. EDRIE-GREEN: Some Observations on the Visual Purple.

THURSDAY, FEB. 6th.

BOSTON SOCIETY (20, Hanover Square).—A Paper will be read by MR. E. W. M. SHENTON, M.R.C.S., L.R.C.P., on a System of Radiography.

DUBLIN.

THURSDAY, JAN. 30th.

BRITISH MEDICAL ASSOCIATION (Dublin Branch).—Annual Meeting, College of Physicians, 4.30 p.m.

FRIDAY, JAN. 31st.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Anatomy, College of Surgeons, 8.30 p.m.

SATURDAY, FEB. 1st.

ROYAL COLLEGE OF SURGEONS.—Examination for L.R.C.S. for registered practitioners.

MONDAY, FEB. 3rd.

DUBLIN UNIVERSITY.—Final Medical Examination in Mid. B.A.O. and M.A.O. Degrees.

TUESDAY, FEB. 4th.

ROYAL CONJOINT COLLEGE.—Examination for D.P.H.

Appointments.

BEDFORD, G. H., L.S.A., Medical Officer of the Rothbury Union.
DENT, HOWARD, M.B.Durh., F.R.C.S. Eng., Assistant Surgeon to the Wolverhampton and Staffordshire General Hospital.
EBSKITH, A. M.C., M.B., B.Ch.R.U.I., Medical Officer to the Gloucester Urban Council and Superintendent of the Fever Hospital at Goolse.

GOVER, J. MAXWELL, M.B., B.S.Durh., M.R.C.S., L.R.C.P.Lond., Medical Officer to the Gosforth District of the Castle Ward Union, Newcastle-upon-Tyne.

GREENWOOD, C. H., M.B., Ch.B.Vict., Resident Casualty Officer to the Leeds General Infirmary.

JACKSON, ARTHUR M., M.D.Oxon., M.R.C.S., Medical Superintendent of the Notts County Lunatic Asylum.

LITTLEWOOD, J. O., M.R.C.S., L.R.C.P.Lond., D.P.H., Visiting Medical Officer to the Nottingham and Nottinghamshire Sanatorium for the Treatment of Consumption, Sherwood Forest, Mansfield.

O'CONNOR J. E., M.B., B.S.R.U.I., Medical Officer of Health for the Urban District of Wigan.

THOMPSON, WM. ATKIN, M.R.C.S.Eng., L.R.C.P.Lond., House Surgeon to the Rochdale Infirmary.

Vacancies.

Bradford Royal Infirmary. Dispensary Surgeon. Salary £100 per annum, with board and residence. Applications to William Maw, Secretary.

County Asylum, Chester.—Third Assistant Medical Officer. Salary £160 per annum, with board, lodging, and washing. Applications to Dr. Lawrence, County Asylum, Chester.

Durham County Asylum.—Junior Assistant Medical Officer. Salary £140, with board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Apply to Dr. Finch, the Asylum, Salisbury.

Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist. Salary £175 per annum, with furnished quarters, attendance, coal, gas, garden produce, milk and washing. Applications to F. Pritchard Davies, M.D. Superintendent.

London Hospital, Whitechapel, E.—Assistant Director of the Pathological Institute at this Hospital. Salary £200 per annum. Applications immediately to G. Q. Roberts, House Governor.

Manchester Corporation.—Mossall Fever Hospital.—Third Medical Assistant at £100 per annum, with board and lodgings. Applications immediately to the Chairman of the Sanitary Committee, Public Health Office, Town Hall, Manchester. Wm. Henry Talbot, Town Clerk.

Metropolitan Asylums Board.—Assistant Medical Officer to the Fever and Small-pox Hospitals. Salary commencing at £160, with board, lodging, attendance, and washing. Immediate applications. (See advt.)

Poplar Hospital for Accidents, Poplar, E.—Resident House Surgeon. Salary £135 per annum with board and residence. Applications to Edw. Feneran, Lt.-Col., Secretary and House Governor.

St. Pancras and Northern Dispensary, 126, Euston Road.—Resident Medical Officer, Salary £105, with residence and attendance. Applications to Hon. Sec., H. Peter Bodkin, 23, Gordon Street, Gordon Square, W.C.

Stepney Union.—Dispenser for the Dispensary, Barnes Street, Stepney, E. Salary £120 per annum. Applications to S. A. Lewis, Clerk, Guardians' Offices, Barnes Street, Barchiff, E.

Westminster General Dispensary.—Resident Medical Officer. Salary £120 per annum, with rooms, gas, coal, and attendance. Applications to Frederick Dawkins, Secretary, 9, Gerrard Street, Soho, W.

Whitechapel.—Eastern Dispensary, Leman Street.—Resident Medical Officer. Salary £140 per annum, with furnished residence, coals, and attendance. Applications immediately to George W. Halsey, 60, Great Prescott Street E. (See advt.)

Births.

ANDERSON.—On Jan. 25th, at Faversham, Kent, the wife of Charles Macdonell Anderson, M.D., of a daughter.

BRYDEN.—On Jan. 23rd at 21, Harmer Street, Milton-next-Grave, the wife of Surgeon-Captain R. J. Bryden, Army Med. Reserve, of a daughter.

HARRISON.—On Jan. 22nd, at St. James's House, Daventry, the wife of Dr. A. Everson Harrison, of a daughter.

HUBBARD.—On Jan. 20th, at 69, Barrowgate Road, Chiswick, the wife of A. J. Hubbard, M.D., of a son.

REES.—On Jan. 22nd, at Craig-y-Rhedyn, Pontardawe, Glamorgan-shire, the wife of J. Llewellyn Rees, M.R.C.S., L.R.C.P., of a daughter.

Marriage.

WALTERS—HARRISON.—On Jan. 23rd, at Mertham Parish Church, A. E. Walters, M.R.C.S., L.R.C.P., of Reigate, Surrey, to Evelyn Janet Newman Harrison, of Little Santon, Mertham, daughter of the late Rev. John Newman Harrison, for fifty-three years Vicar of Reigate.

Deaths.

TURNBULL.—On Jan. 23rd, at 17, Alton Road, Oxton, Cheshire, Margaret Maxwell, widow of the late Dr. James Muter Turnbull, F.R.C.P., of Liverpool.

WEIR.—At Guy's Hospital, on Jan. 26th, from an accident, Arthur Nesham Weir, M.D., F.R.C.S., aged 33, elder son of James and Mary Jane Weir, of 55, St. Charles Square, North Kensington.

CHRONIC PROGRESSIVE DEAFNESS:

ITS CAUSATION AND TREATMENT.

By MAYO COLLIER, M.S. Lond., F.R.C.S. Eng.,

Senior Surgeon to the North-West London Hospital, and Ex-President of the British Laryngological, Rhinological and Otolological Association, &c.

SLOWLY progressing deafness unassociated with ear disease is an extremely common affection. My authority for this statement is my own personal experience extending over a period of eighteen years. This experience was in large part gained at the North-West London Hospital, from an extensive out-patient department, amounting to sometimes 100 patients per week. Next from the work and writings of others who have had similar extensive personal experience.

For instance, Dr. Sam Seaton, of New York City, no mean authority, whose life-long labours in the field of aural diseases should be better known to those claiming even a superficial acquaintance with the literature on this subject, says, in his article in "Burnett's System of Throat, Nose and Ear Diseases," when speaking of chronic middle ear disease unassociated with suppuration:—

"One point of interest is the extraordinary frequency of this affection. One-quarter to one-third of all ear diseases are of this nature, and probably a larger proportion from the fact that only the advanced cases apply for relief."

He goes on to say, or words to that effect:—

"That the absolute frequency, as measured by the number of cases in the total population, is very great."

"The majority of people have some involvement of the middle ear, and a majority of this majority, chronic progressive deafness to a greater or less degree, as the case may be."

These statistics are Dr. Sam Seaton's, not my own.

Neither he, nor I, nor anyone else (except some unscrupulous, careless persons who have intentionally misquoted me) has stated that a majority of the inhabitants of the temperate regions were deaf.

My statement was on the authority of Dr. Sam Seaton, and, was as above quoted, viz., "A majority of a majority" were more or less deaf.

The accuracy or inaccuracy of these statistics is a matter of no moment. The fact remains the same, that chronic progressive deafness is a condition prevalent among all classes and ages of society in these regions.

The man in the street will tell you this. The policeman round the corner, or the cabman on the rank will tell you that he, or one, or more of his friends is hard of hearing, and slowly becoming worse, and that he has never had pains, aches or trouble in his ears.

The terms chronic middle ear catarrh, chronic sclerosis, chronic non-suppurative disease of the middle ear include certain conditions—the result of previous catarrh, suppuration, congestion, or injury of, or in, or about, the middle ear.

The affection I propose to deal with more particularly

in this communication is the form of deafness that occurs quite insidiously, without warning, without pain, or discomfort in the ears, and only becomes apparent to the individual when a marked impairment of hearing has taken place. I propose to call this in contradistinction to cases of deafness secondary to ear diseases "Chronic progressive deafness."

To understand the etiology of this affection, as indeed most of the affections of the upper respiratory tract, some knowledge of the laws of physics and pneumatics is requisite.

The most astonishing ignorance of the elements of pneumatics is constantly displayed by writers on this subject. It is actually denied that the tension of the air in the tympanic cavity must be the same as the outside air to ensure a free and normal vibration of the drum-head. The mechanism of a cupping glass seems to be quite unknown to some.

It is also contended that obstruction to the free inlet of air to the tympanic cavity produces no difference in the tension of the air contents of that cavity, and it is considered to be quite a new theory that, if the normal extravascular pressure be diminished in the tympanic cavity, the intravascular pressure will assert itself by dilating the vessels and tissues generally of the structures under lessened pressure.

Since the world began this has been so, and yet there are apparently some individuals who are not yet aware of this elementary fact. The non-recognition of this simple elementary fact is the reason why all sorts of extraordinary statements are made in reference to this affection. The most prevalent is that the catarrhal process always invades the tympanum. It is impossible for the catarrhal process to invade the middle ear from the pharynx without producing three at least marked symptoms—two subjective, one objective—marked deafness, with pain or discomfort in the ear, and thirdly, the presence of fluid in the tympanic cavity, as seen through the drum-head.

This is said by some to be a dogmatic assertion. All self-evident truths may be called dogmatic assertions. One can in this case speak dogmatically, because the fact is self-evident. The catarrhal process in its very essence consists of an outpouring of fluid. You cannot have catarrh without an outpouring of fluid.

You cannot have an outpouring of fluid in the tympanic cavity without pain, deafness, and its presence being apparent on examination of the drum-head.

Yet in the cases under consideration at no time is there pain, and the deafness is not sudden and pronounced, and there is no evidence of fluid in the middle ear at any time.

No, this argument is not sufficient for gentlemen who style themselves as "not otologists," and gentlemen who announce their claims to speak with authority, as resting apparently on the fact of their residing in the Provinces or remote parts of the country, where their researches or experiences as otologists cannot be exhausting or exhaustive. I believe it is not requisite to import any unsound or reckless assumptions to explain the cause of this affection, and in order to be not dogmatic and strictly scientific I will endeavour to place my argument *in extenso* before my

readers, as I did in my paper on the subject at the Cheltenham meeting of the British Medical Association.

I stated there that I had arrived at the conclusion that a very large percentage of cases of so-called sclerosis of the middle ear (or, in other words, all those cases of chronic progressive deafness unassociated with middle ear disease) were a concomitant and direct result of ordinary nasal catarrh from simple mechanical obstruction of the Eustachian tube, and that the early recognition and treatment of these cases often result in a satisfactory and permanent improvement of hearing.

My first point is that the tympanic cavity is part of the nose, both anatomically and developmentally, and that affections of the nose and tympanum have a close affinity. Both the tympanic cavity and the other cavities leading from the nose are anatomically parts of, and extensions from, the nose cavity, and any alterations in the physical condition of the contents of the nose cavity will be communicated to, and affect the patent extensions from this cavity.

Under normal circumstances the contents of each cavity have a free intercommunication. The tension of the air in the nose is the same as the tension of the air in the tympanic cavity, and the same as the tension of the air in the surrounding atmosphere. The tubo-tympanic cavity is a part of the upper air passages as much as the antrum or any of the accessory cavities of the nose.

It is lined with an extension of the same membrane that lines the nose, and is covered with the same sort of ciliated epithelium, but differs in this one respect that it partakes of the character of, and is virtually a peristomeum.

This difference in the constitution of the lining of the tubo-tympanic cavity greatly increases its importance, both physiologically and pathologically.

Embryology shows us that the Eustachian tube and tympanum with its extensions upwards to the attic or epi-tympanic space, and backwards to the antrum or post-tympanic space, are one complex and slowly developing extension from the oro-nasal cavity, and are completely separate from the internal ear or ear proper. On these anatomical and developmental grounds I desire to emphasise the fact that the tympanic cavity is part of the nose cavity, and is only accidentally related to the internal ear or ear proper.

It is necessary when studying the anatomy, physiology, and pathology of the tubo-tympanic cavity to look upon it as part of the nose cavity, and as sympathising with, and sharing in, the variations in the conditions of the contents and diseases of the nasal cavities.

I believe that in the associated conditions of a chronic cold in the head, with partial obstruction to nasal respiration, you have every factor requisite to produce in a great majority of cases the condition known as sclerosis of the middle ear, or, as I prefer to term this, chronic progressive deafness.

Do not forget that the tympanic cavity belongs to the nose, that the tubo-tympanum is an extension of the nose cavity, that it is practically always open and always freely communicating with the nose; that the tension of the air in this cavity is normally the same as in the nose, and the same as in the outside air.

What is likely to take place if the means of free communication between these spaces is altered or curtailed? In the event of the free communication being cut off by obstruction to the mouth or lumen of the Eustachian tube by catarrh or any other causes, the air contents of the tympanic cavity would be partly absorbed. The drum-head would then, as a necessary result, be driven in "to accommodate the cavity to its lessened contents." The vessels in the lining membrane of the walls of the tympanum being no longer under normal external pressure become dilated from unbalanced intravascular pressure. This means swelling and redness of the whole of the tympanum, and in cases of sudden and complete obstruction to the Eustachian tube, such as occur in a bad nasal and post-nasal catarrh, serous effusion into the lining membrane or even into the tympanic cavity.

With the lesser degrees of Eustachian obstruction, the lesser grades of congestion of the lining of the middle ear are associated. It is a matter of common knowledge that a bad cold in the head will make the individual quite deaf, sometimes for weeks. In this case there is always complete obstruction to the Eustachian tube, and the air contents of the tympanum are so diminished as to cause a considerable diminution of its cavity by sinking in of the drum-head.

In addition to this in quite a number of cases serous fluid exudes into the drum cavity from its congested lining membrane.

If we look at the drum-head whilst in these conditions we find the membrane very depressed, with pockets in front and behind the handle of the malleus. We see the short process bursting through the membrane, and the handle of the malleus very oblique. The drum-head is angular instead of concave. The colour is normal below, in the lower segment, but above, in the region of the handle and head of malleus it is red and striated with vessels passing down to the umbo. In the more acute form of Eustachian obstruction, there is more redness and more depression, marked or complete deafness, noises in the ears, and evidence of fluid in the tympanic cavity.

The lesser degrees of obstruction to the Eustachian tube are sufficient to produce the condition of chronic progressive deafness. In this condition there is always a little extra pressure on the outside of the tympanic membrane that hampers its movements. There is always a slightly lessened pressure on the inside of the tympanic membrane that dilates its vessels, increases its weight, thickens its tissues, and alters its transparency. This slightly lessened pressure on the lining membrane of the walls of the tympanum and coverings of the ossicles causes similar changes.

The lessened excursions of the drum-head affects the joints of the ossicles, and in time stiffness and ankylosis supervenes.

The increased pressure on the stapes is communicated to the labyrinth, and noises of various kinds is the result. Chronic partial obstruction to the free supply of air to the tympanic cavity is thus seen to be all-sufficient to produce the altered physical condition of the tympanic cavity that corresponds to the impaired hearing in chronic progressive deafness.

My next point is that these cases are not all incurable.

I have stated that it is my experience that the early recognition and treatment of these cases often result in a permanent and satisfactory improvement of hearing.

I have gone further than this, and stated that in the routine work of hospital practice, where every case of chronic sclerosis received treatment, quite a considerable percentage of cases apparently hopeless improved. It is quite a common experience of old cases of chronic progressive deafness to find the nasal cavities quite healthy, and the Eustachian tube quite patent or even abnormally patent. The catarrh has done the mischief and subsided.

This is no argument against the contention that nasal catarrh with partial or complete obstruction to nasal respiration is the antecedent in most cases to Eustachian obstruction, and so to chronic progressive deafness.

Complete nasal obstruction in some cases is not associated with post-nasal catarrh, but in the vast majority of cases it is so.

The vast majority of people would suffer from gastric catarrh if they swallowed nails, corks, tops of bottles and swords, but the sword swallower does all this apparently with impunity. It is quite childish to argue a "general" from a particular. Some persons can consume 120 grains of arsenic a day, but nobody in his senses would contend that 999 persons out of 1,000 would not be poisoned by this amount.

It is the commonest experience with those versed in nasal surgery that a plug in the nose will set up a catarrh in the post-nasal space, and will cause temporary deafness till the plug is removed, when in a few hours the hearing is restored.

A plug of cotton wool placed in a perfectly healthy nose would in forty-eight hours produce a severe nasal

and post-nasal catarrh and probably deafness. The method of treatment adopted by myself in these cases has in view the removal and cure of the catarrh in the nose and post-nasal space, and the restoration of the free inter-communication between the post-nasal and tympanic contents. Where marked solid obstructive conditions exist in the nose, if they sufficiently interfere with nasal respiration so as to influence and keep up the catarrh they should be removed, but not otherwise. The obstruction keeping up the catarrh is, in a great majority of cases, due to turbinal atony.

This obstruction is episodal in character. During many hours the nose is quite free, but at night and at other times it is often completely blocked. This latent form of nasal obstruction is the great stumbling block of the "non-possumus" school of otologists.

A case presents itself with marked impairment of hearing of a slowly progressing character, without a history of any pain or trouble in the ears. On examination the drums are depressed and somewhat opaque, with, perhaps, redness near the head and down the handle of the malleus. The nose on examination is quite free, often abnormally patent. The mucous membrane is injected and sticky.

Here, says the provincial Solon, is chronic sclerosis of the middle ear with a perfectly free and patent nose. Good, easy man, look on the septum. What is that depression corresponding to the convexity of the lower turbinal body? It is a fossa made by the turbinal body when it is distended, as it is every night, or whenever the patient assumes an horizontal position, and on many other occasions. Look in the pharynx. What are those patches of atrophy with dilated veins and islets of enlarged gland substance? They are the result of chronic hypertrophic pharyngitis, the outcome of mouth breathing.

Now try your patient with the Politzer bag. You will in many cases fail to get air in. The Eustachian opening is obstructed. After an antiseptic and astringent wash, perhaps in a week's time, air will enter. The galvano-cautery will put a stop to this latent obstruction, and will do more, it will relieve the congestion of the nasal and post-nasal space by letting in the air.

The galvano-cautery will also give tone to the vessels of the post-nasal space and tympanum. The nose being ventilated and the patency of the Eustachian tube restored, the drum-head should be daily exercised by gentle movements imparted by Politzer's bag and Seigle's aspirator.

This treatment is simple and in conformity with the etiology of this affection, and in a large percentage of cases results in a marked and permanent improvement of hearing.

Harley S treet, Jan. 30th, 1902.

THE FUTURE OF THE ARMY MEDICAL SERVICE. (a)

By C. B. BALL, M.Ch., F.R.C.S.I., Hon. F.R.C.S.Eng.,
Regius Professor of Surgery, University Dublin; President of the
Dublin Branch of the British Medical Association.

IN choosing a subject upon which to address you today, I thought that the suggested reorganisation of the Army Medical Service in which our Association has taken such a wide interest, was the one to which public attention is at present most markedly attracted, and more particularly, possibly, to us in Ireland as the Army has always been a career favoured by our young Irish graduates in medicine.

Upon turning to the Army List published last month, some interesting and to me somewhat unexpected facts were revealed. In the first place, the total number of officers, from the Director-General to the last-joined lieutenant of the R.A.M.C., is 987, or over 100 more than the full strength of the Corps before the war, not including the large number of civilians at present doing temporary duty at home, and in South Africa. This large surplus must, however, to some extent be discounted by the fact that it includes thirty officers of the

reserve, and that resignations have been interrupted during the progress of the war, but even allowing for these, it will probably be found at the termination of hostilities that the corps is considerably above its normal strength, and not in the depleted state that many of the critics would have us believe. That a permanent increase of the strength for the future is necessary is, however, fully recognised.

When we come to investigate the schools from which the officers have come into the Service, as evidenced by the "Medical Register," or in some cases by Churchill's "Medical Directory" for last year, we find the following interesting entails:—

Officers whose qualifications are all Irish ...	352
" " " " " English	305
" " " " " Scotch	221
Officers whose qualifications are obtained in more than one division of the United Kingdom, of whom thirty-two have at least one Irish qualification	100
Officers whose qualifications are not to be found in "Medical Register" or Churchill's "Directory, 1901"	9
	987

(This last item is chiefly made up of recently-joined lieutenants.)

It will thus be seen that Ireland has sent into the Service a considerably larger number of officers than England or Scotland.

When, however, we come to see the proportion of the different nationalities in the various ranks of the corps, some further interesting particulars are brought to light.

The present Director-General has Scotch qualifications.

	P.c.	
Of 8 Surgeons-General	75	have Irish qualifications.
Of 27 Colonels ...	77.7	" "
Of 206 Lieut.-Colonels ...	48.8	" "
Of 284 Majors ...	35.1	" "
Of 227 Captains...	24.2	" "
Of 234 Lieutenants	37.6	" "

It will thus be seen that among the higher ranks the Irishmen largely predominate, while among the lower ranks there is a marked falling off in the number of those who possess qualifications from the Irish licensing bodies. A study of these figures shows in the first place that Irish graduates have been in the past highly successful in obtaining the highest ranks in their profession, but I fear it also proves that of recent years the Service has not been so popular upon this side of the water as it used to be.

During the time Lord Lansdowne was Secretary of State for War, he, upon several occasions, showed the keen interest which he took in the welfare of the Army Medical Department, and many and important reforms have followed, when grievances from which medical officers undoubtedly suffered were brought under his notice. At that time students who obtained their qualifications in Ireland found it absolutely necessary to go for some months to a grinder in London if they desired to obtain a good place at the entrance examination, the character of the London examination being different and in some respects, I believe, inferior to that to which they had been accustomed in Ireland. Upon this matter being brought under the notice of Lord Lansdowne, Prof. D. J. Cunningham, of Dublin University, was placed upon the Examination Board.

Again, in January, 1898, a deputation organised by the British Medical Association, and upon which I had the honour of representing Dublin University, waited upon Lord Lansdowne and urged what undoubtedly at the time was the greatest grievance of which the medical officer complained—the want of substantive rank in the Army, and the formation of the Army Medical Staff into a Royal Corps. These reforms were shortly afterwards granted, and it was quite evident from the way in which the Secretary of State for War received and spoke to the deputation that he was much in earnest in his desire to remove all reasonable causes of complaint and render

(a) An Address delivered at the Annual Meeting of the Dublin Branch of the Medical Association, Jan. 30th, 1902.

the Service again attractive to a good class of young medical men.

But since these changes were made, the market price of medical men has gone up, and the question of pay, which three or four years ago was not really complained of except during service in India, has become a prominent one; the marked increase which has taken place in the salaries to the assistant and locum tenens of the general practitioner naturally drew attention to the pay of the R.A.M.C., and the newly qualified man hesitated to join the army, when he had abundant opportunities of being employed with fair remuneration in civil practice. As has been frequently pointed out this dearth of, and consequently enhanced value of, newly-qualified practitioners is due largely to the abolition of unqualified assistants in general practice and to the prolongation of the course of study to five years, which so greatly adds to the cost of production of the qualified practitioner; but as a cause of a more temporary character which has been much overlooked is the fact that the change from four to five years' curriculum practically obliterated an entire year's supply of graduates, a loss which was felt for several years, as the five years' students gradually blended with the old four years' men.

The present war has directed attention to the army doctor again, and the Secretary of State for War has approached the question in a broad and statesmanlike spirit, and appointed a Committee to inquire into the entire question of reorganisation of the corps, a committee upon which Sir William Thomson ably represented Irish interests. The report of this committee has now been before the public sufficiently long for its propositions to be thoroughly well criticised and discussed. I propose, therefore, to review some of its more important features.

First, as to increased pay:—The proposals made by the reorganising committee in this respect seem to have met with universal commendation. Formerly a lieutenant on probation at Netley received 5s. a day, a sum insufficient to pay his necessary expenses, and when he obtained his commission he received £200 a year with allowances. Under the new suggested scheme he will receive £250 a year, both as probationer and lieutenant, with allowances, valued at 27s. 10s., making a total of £323 a year, increased at the end of three years' service to £379 15s. 2d., and so on through the higher ranks there is a liberal increase provided for; but besides the actual pay the officer is building up during his service a substantial sum either in the way of gratuity or pension, while in the higher ranks provision is made for widows and children of officers who die during their period of service. The deferred pay under the new scheme will be at the rate of a gratuity of £1,000 after nine years' service, £2,500 after eighteen years' service, and a pension of £1 per day after twenty years' service. The pension will be subsequently augmented according to rank and length of service, as previously provided for. Owing to the wording of the report of the reorganising committee it was thought that if the officer failed to pass the examination recommended for promotion to the rank of lieutenant-colonel before he reached twenty years' service he might be compulsorily retired upon the gratuity of £2,500 without the option of completing his twenty years' service, and so becoming, under existing rules, entitled to a pension of £1 per day. This possibility excited widespread dissatisfaction among the officers of the R.A.M.C.; in fact, it was the one subject in the report upon which disapproval appeared to be quite unanimous. I am enabled, however, to state upon authority that it was never intended to deprive officers of the right to this pension, even if they failed to pass the suggested examination for promotion to lieutenant-colonel.

Besides the pay above alluded to, officers who qualify as specialists in any one of a comprehensive list of subjects will be entitled to an additional 2s. 6d. per day, while those in charge of hospitals will be entitled to extra pay varying from 10s. per day if the hospital contains 300 beds, down to 2s. 6d. if it contains only fifty beds.

The question of increased pay while serving in India, which has long been a grievance, will, it is hoped, be

satisfactorily settled by the Indian Government, but no statement to that effect has as yet been made public.

The necessity of periods of study-leave has long been urged, and its importance admitted by the authorities, but hitherto the exigencies of the Service have prevented its being granted to the extent which is undoubtedly required. The reorganisation committee recommend that after three years' service, and before promotion to the rank of captain, the officer is to be "attached for a period of six months to a recognised hospital in a centre where he has opportunities of gaining further professional knowledge by attendance at a course or courses of instruction in a civil hospital, or otherwise as may be approved by the Advisory Board, and upon completion of six years as captain, he shall be afforded a further similar period of six months at a centre where he may have facilities for attending courses at a recognised civil hospital.

In case of an officer desiring to engage in advanced professional study it shall be open to the Advisory Board to recommend that special leave be granted him for a period of six months.

Another recommendation of the committee that has met with approval is that promotion to the higher ranks is to be made through some other means than mere seniority. That officers should be encouraged to devote themselves to the acquiring of professional knowledge, and that they should know that work done in this direction will be rewarded by accelerated promotion, appears to me to be the most essential reform if the army is to be looked on as a career which will attract a good class of men. That the present arrangement is not satisfactory is an admitted fact. No doubt among the officers of high rank are many who take a keen interest in encouraging young officers under them to occupy themselves with scientific pursuits, and where good work has been done, to notify such to headquarters by confidential report or otherwise; but that the contrary is also sometimes true is notorious, and the energetic young officer finds anything but encouragement from his superiors, and soon learns that the way to reach the higher ranks is to have nothing said against him, but otherwise to do as little as possible.

It is only in the nature of things that men who have risen to executive rank simply by living long enough and having nothing said against them are not the most likely to encourage and stimulate young officers to hard work at their profession.

The report of the reorganising committee shows that this subject has been fully considered, and suggestions have been made that a series of examinations should be held immediately preceding each step of promotion to the rank of lieutenant-colonel; failure to qualify at any of which after a second trial, will lead to compulsory retirement from the Service; while, upon the other hand, brilliant answering at the earlier examinations will lead to acceleration of promotion of from three to eighteen months according to the percentage of marks obtained. This suggestion of examinations up to the eighteenth year of service has been very adversely commented on by officers and others, and it is probable that when the warrant appears certain changes will be made. The verdict of the profession at large, which is fully endorsed by the public, is that if the Service is to be made attractive to young graduates and thoroughly efficient for the important duties it has to discharge professional merit must be acknowledged and lead to accelerated promotion. But how is this to be done? By examination say some, and if the examination is the right sort there is much to recommend it, but it should be carried out not in the form of a students' examination, which is to be passed by so many months' grinding for this special purpose, but rather by one conducted on a definite principle by examiners whose duty it must be to find out what use the candidate has made of the opportunities of purely professional work he has had at his disposal, and to what special scientific branches he has most devoted himself. If carried out in this way it has the great advantage of uniformity; while the alternative of relying upon reports sent to the Director-General from all parts of the world by superior officers which vary

enormously according as to whether the superior officer with whom the subaltern is serving happens to be a man of enlightened scientific mind, or one whose only idea is to carry out what is contained within the four corners of the regulations.

A suggestion which has been made by the reorganisation committee, but which has received little notice from the critics, appears to me one of the most important of all; it is the establishment in London of a large Military Hospital with Staff College attached. This hospital will differ from Netley and others of similar character in the fact that it is intended more for acute cases of illness and accident, such as are met with in the great clinical hospitals; the invalids returned from abroad and cases of chronic illness being largely treated elsewhere. The supply of cases will come from the London garrison; soldiers' wives and families, War Office employees, and in cases of accident and emergency, civilians. Recruits who are ineligible for admission to the army in consequence of hernia, varicose veins, varicocele, and other similar conditions, will be taken in in order to undergo operation, so that they may qualify for enlistment. In this way it is thought that an abundant supply of clinical material, not only in medicine and surgery, but also in the various special departments will be forthcoming. A professional staff, with numerous assistants, will be appointed from the R.A.M.C.; while the Staff College will afford opportunities for the training of lieutenants, probationers, and also of officers for periods of study and practical work during their term of service. As this hospital will be in London, it will be under the eye of the Director-General, and a very much more correct judgment of the professional capabilities of officers can be obtained during their periods of service at this hospital than can possibly be done by any system of examination or reports of individual superior officers.

I believe all fair-minded people will admit that the work done by this committee at the instigation of Mr. Brodrick is an honest and broad-minded endeavour to place the R.A.M.C. in the position which we all wish to see it occupy.

What are the prospects likely to attract young graduates into the Service? Men likely to get appointments on the staff of general and special hospitals other than the post of house surgeon are not likely to seek the army as a career, but as contrasted with country private practice, except in favoured districts, it appears to present many solid advantages, more particularly so when compared with the miserably hard and underpaid lives which so many dispensary doctors in Ireland lead.

The officer of the R.A.M.C. commences with a fair salary, he sees the world, and if after a few years he desires to settle down into private practice, he can retire upon a gratuity probably considerably in excess of any sum he could have saved if he were engaged in civil practice for the same period, while after twenty years he can retire on a pension of £1 per day, and, if he so desires, start in any branch of the profession he may wish. To those to whom distinctions and decorations are an attraction, it may be interesting to know that six officers of the R.A.M.C. hold the much-coveted honour of the Victoria Cross, three hold the K.C.M.G., sixteen the C.B., twenty-five the C.M.G., and twenty-nine the D.S.O. There are many men who are fond of their work, but who hesitate to enter the army as it affords, in time of peace at any rate, so little scope for practical work. That this is to some extent true is an undoubted fact, and it is one of the great difficulties that the Service has to contend with—a difficulty which, to some slight extent at any rate, will be diminished by the establishment of the large hospital in London. But even if the opportunities of practical medicine and surgery may be small, there are always opportunities of doing good work in hygiene, bacteriology, and, on foreign service, tropical disease, or other similar subjects in which a really sound scientific reputation may be made. It is only necessary to mention the names of Lieutenant-Colonel Bruce, F.R.S., of the Royal Army Medical Corps, the discoverer of the cause of Malta fever, and of horse sickness in South Africa; or of Major Ross, late of the Indian Medical

Service, whose work on the relation of mosquitoes to malaria is notorious, to show that medical officers in the army have opportunities of scientific research in some directions far greater than can be enjoyed by their civilian brethren, and that among the officers are to be found men capable of utilising those opportunities to the utmost, and of gaining, not only for themselves, but for the Service to which they belong, a well-merited scientific reputation.

CASE OF TUMOUR OF THE LEFT PRE-FRONTAL LOBE REMOVED BY OPERATION. (a)

By WILLIAM ELDER, M.D., F.R.C.P.ED.,

Physician to the Leith Hospital;

AND

A. MILES, F.R.C.S.ED.,

Surgeon to the Leith Hospital.

DIFFICULTY arises in the localisation of tumours of the so-called "silent areas" of the brain. Whilst stimulation of the frontal region has given negative results in the hands of competent observers, extirpation of these lobes in monkeys gives rise to symptoms closely resembling those of this patient, as well as of other reported cases. The patient was a man, *æt.* 47, who, six months before admission began to complain of pain in the head, which was localised in the left frontal region during the greater period of its duration. He had also aching in the back and shooting pains in the legs. Early in the course of his illness a swelling developed in the left side of his forehead, which disappeared after he took some potassium iodide that had previously been prescribed for him. He continued at work for five months, and then became depressed and refused to leave his bed, his memory was impaired, he became emotional, he lost all sense of decency, and had incontinence of urine. On admission he was dull and could be aroused with difficulty. Hearing was normal and he answered questions correctly though slowly. His attention was imperfect, and his memory bad. The loss of memory depended rather on inability to associate recollections than on a complete blotting out of past events. There was slight dysarthria. He was illiterate, so that reading and writing could not be tested. There was paresis of the right side of the face and the right arm. Ankle clonus was present. Beyond some giddiness there was no incoordination, and he walked easily. The left eye had previously been destroyed by small-pox. Vision good in right eye and pupil normal. He often made mistakes in counting fingers, and answered questions as if he took no interest in them, and often incorrectly and in a contradictory manner. The only other point worthy of mention was the existence of a small tender swelling, arising from the bone in the left frontal region. There was evidence of previous syphilis. Very shortly after admission he became semi-comatose, and his breathing was stertorous and Cheyne-Stokes in character. At 8.30 p.m., on Oct. 13th, he was seen to have difficulty in swallowing, and his breathing became worse. Percussion over the swelling in the frontal region caused wincing. The veins of the fundus were dilated and the disc blurred, but there was no neuritis. At 10 p.m. Mr. Miles operated, as the patient was growing very rapidly worse. A small carious area was found on the left frontal bone, only the outer table being affected, and the inner aspect normal. The dura was thickened, and by its bulging gave evidence of intracranial tension. On opening the membrane the brain did not pulsate, and a firm nodular mass was found occupying the tip of the left frontal

(a) Abstract of Paper read before the Edinburgh Medico-Chirurgical Society, January 15th, 1902.

lobe. It was circumscribed and could be readily shelled out, after which the brain pulsated freely, and the cavity left by the tumour was immediately filled by brain tissue bulging into it. The tumour was lobulated, firm, and measured 2 ins. by 1½ ins. by 1¼ ins., and had the microscopic structure of a gumma.

Progress.—Next day the patient could answer questions and knew where he was. The following day he spoke voluntarily, was unnaturally bright and lively, his condition resembling that of slight intoxication. He voluntarily controlled his bladder, and asked for the bed-pan as he required it. On the third day he became emotional, and began to use bad language. On the sixth day, though still emotional, he began to take interest in events which had occurred during his illness, and on the twenty-eighth day he was well and allowed up, and has remained in good health since.

Dr. Elder said that his diagnosis was based on the fact that the symptoms were cerebral, for the incontinence of urine and, latterly, of faeces was analogous to what one sees in dementia, and was associated with a loss of the sense of shame. Dementia, however, was excluded by the history of six months only, and hæmorrhage, thrombosis, or embolism, by the absence of any history of paralysis, since these conditions almost always affect the motor regions chiefly, whereas here the symptoms pointed to the frontal lobe being involved. Abscess was excluded by the temperature and the absence of leucocytosis. The symptoms suggesting tumour were the gradual onset, with signs of increasing intra-cranial tension, together with the blurred disc. The tumour was localised at the left side by the slight right paresis, with dysarthria, but no aphasia, the face being more affected than the arm. From this it was inferred that while Broca was spared, the fibres from the lower part of the Rolandic area to the internal capsule were implicated. This localisation was supported by the external swelling, which might not unlikely have been associated with a gumma on the inside of the skull. Taken with these, the facts that his psychology was so greatly altered, that there was loss of inhibition, peculiar faults in the faculties of memory, and of attention, all pointed to the lesion affecting the frontal lobe. The time had now come for discarding the idea that the pre-frontal lobes were silent regions. Probably the left lobe was more important for higher cerebration than the right, but into this question the author does not wish to enter. The "hilarity" which succeeded the operation has been previously described as an accompaniment of frontal tumour, but probably, Dr. Elder observed, was so only before the intra-cranial tension rises. It is probably due to slight injury to the structures concerned with voluntary inhibition, and seems allied to the results of taking moderate amounts of alcohol.

WHY WE OPERATE IN MALIGNANT DISEASE ?

By F. A. PURCELL, M.D., M.Ch.,
Surgeon to the Cancer Hospital, London.

THIS is a very serious question, to which, as practical surgeons we will endeavour to give an explicit answer.

Despite every effort to prove the contrary, authorities are now generally agreed that the death-rate from malignant disease is greatly increasing, and that this increase is real and not merely apparent. That there are real grounds for this anxiety anyone can determine for himself by glancing at the mortality rates for cancer in the Registrar-General's

returns for the last two or three decades. According to the report of the Registrar-General for 1895, of 1,000,000 of the population 755 died of cancer. The melancholy array of these figures, showing the alarming increase in the mortality of cancer, places us in the position of having to face a problem which cannot fail to become more and more serious with the advance of time. Malignant disease demands therefore the serious attention of investigators.

In cancer we find a horrifying display of human anguish, a disease which tends to destroy everything which is good, both in man's soul and body, and one which can, and does, inflict fiendish suffering; those afflicted look forward with eager impatience to the release which death alone can bring.

Two theories have been, and still are, held as the essential nature of cancer: (a) the embryonic or evolution theory; (b) the parasitic theory. In support of the former are many sound observers. The more fascinating, and probably the more correct theory of malignant disease is the parasitic. The position of our knowledge with regard to cancer and its causes is terribly serious. For some years great and painstaking efforts have been made by certain bacteriologists, both in this country and abroad, to demonstrate its micro-organic origin, but up to the present these researches have proved futile. No cancer bacillus or bug has yet been isolated, more than once some enthusiastic investigator has startled the medical world by the announcement that he had discovered the characteristic organism of cancer, but further investigation by independent observers has proved that an error had been made.

Our pathologist, Mr. H. G. Plimmer, has worked from the material at his disposal given to him from the cases operated on in the Cancer Hospital. His interesting discoveries carry the conviction to our minds that a parasite is present in the active growing cells of most cancerous tumours. He has found these parasites in 1,130 cases out of 1,220. There were reasons why they were not found in ninety cases, and fifty-eight cases remain in which they could not be found. These parasites, however, may follow the commencing stage of the tumour instead of preceding it. If they precede it, which they must do if they cause cancer they ought to be found apart from the disease. Moreover, micro-organisms, as the sole cause, do not harmonise with most of the facts about the disease.

Despite, however, the want of success so far, the bacteriologists who have devoted themselves to this subject continue to prosecute their researches, deriving encouragement from the firm conviction that the development and progress of cancer as a disease so closely accords with the features of an infective malady that the discovery of a characteristic micro-organism must only be a question of time. Perhaps we may propound that the microscope is played out, and for the future we must turn our thoughts to research.

There will, however, be less need for concern as to the real ætiology of cancer were it the case that the disease was not increasing.

Why we operate! If we assume that cancer is in at least some, if not all, cases parasitic in origin, then there must unquestionably be a time when the growth is localised at the point of inoculation, and, if so localised, there can be no doubt that early operative and radical removal is the means of cure, so far at least as that inoculation is concerned. The local deposit of cancer is diffused, as we know, "mainly" through the lymphatic system. With the wide local removal and a clearing away of lymph channels and glands based upon investigations, we should then logically expect to attain more permanent results in the treatment of cancer. That the

treatment carried out, so far as our present knowledge permits us upon these lines has justified the anticipations which were held out, is beyond dispute.

The question then as to the propriety of the use of the knife in malignant disease can be considered permanently settled.

Our efforts must now be directed to a close study of the earliest manifestations of malignant growths in their various sites, and to a laborious and exhaustive investigation of the intricate lymphatic channels.

At present the only known method of relief available for its victims is that which surgery is able to afford; but this is only possible in the early days of the malignant attack. In the latter stages even surgery is powerless to hold out any hope of palliation. Advanced cases of cancer are among the most distressing that a surgeon can be called upon to treat.

With the continued unrestrained and augmenting death-rate from cancer the time seems already present when malignant disease will come to occupy the first place among the mortality records.

Why we operate on the breast? Recent statistics have unmistakably shown that the treatment of cancer of the breast is followed by much better results than used to be the case.

The success of an operation for cancer of the breast is measured by the period at which local recurrence shows itself afterwards, and no doubt the only means we have of judging as to the thoroughness of the procedure practised is by noting the interval which elapses between the operation and the return of the disease.

The real hope for improvement upon the present figures does not rest so much upon an extension of operative proceedings and more perfect technique, but upon an early recognition and early extirpation of the primary focus of invasion. Hence the surgical maxim laid down "that few operations for well-developed cancer can be considered radical unless the removal of the primary growth is accompanied by prophylactic extirpation of the tributary lymphatic areas." (Dr. Matar.)

It is satisfactory to know that since this principle of surgical practice, as applied to carcinoma of the breast, has been followed there has been a great improvement in the results; the evidence upon this point is so definite and indisputable that there is really no excuse for operators refusing to adopt the treatment.

The point is really one of supreme importance, for it must be evident that unless a surgeon is prepared to undertake the complete or radical operation for cancer of the breast, viz., the Heidenhain-Stiles so-called method, carried out by Bennett, Halsted, Meyer, Rotter, Helferich, Watson Cheyne, and by the staff of the Cancer Hospital, such as experience has now proved to be necessary in the interests of the patient, interference on his part would almost be unjustifiable.

My colleague, Mr. C. H. Leaf, has laid stress on taking steps during the operation for removal of carcinoma mammae (*vide Lancet*, November 30th, 1901, p. 1488) to obviate the risk of subsequent dissemination by occluding as far as possible the emergent lymphatics and veins. He maintains that the possible risk of dissemination which may result, either by infection of the wound or by the innumerable lymphatics and veins being cut across, should always be borne in mind and as far as possible provided against at the time of the first operation. His suggestion, and which he has carried out recently in some six cases, is to effect the lymphatics' occlusion by strangling by a series of ligatures the fascia in which they run, and not to remove the breast till this is done.

The failure by surgeons of the old school was want of knowledge of the manner in which cancer spreads, and the importance of the lymphatic system.

Scirrhus, or true cancer, now designated carcinoma, is of an epithelial type and spreads by means of the lymphatic system, whereas sarcoma, of connective tissue origin, spreads by the capillary system.

The form of malignant disease is absolutely necessary to be certain of in our prognosis, for in carcinoma or duct cancer the chances of recurrence are very much less when only a distinct nodule is located in the breast, whereas in cases of soft, rapidly-growing scirrhus recurrence is much more likely to take place. But in atrophic scirrhus we have noticed operation possibly to do more harm than good, as should recurrence in the skin occur, as often happens, it is probably certain it may take on a more active growth, for the disease, which has been growing only slowly, may take on action and increase very rapidly.

In sarcoma the risk of recurrence is less if seen and operated on early, but once the capsule be ever so slightly burst, the diffusion of the disease by means of the capillary system is rapid, and no portion of the body but may show its counterpart.

I recall a case of osteo-sarcoma of the leg in a boy, named Charles H—, æt. 19; the drawings appeared in the *Illustrated Medical News* (p. 1, vol. 2), and his leg is in our museum. Eight months previous to admission he fell over a stable bucket, a tumour developed in his leg, which increased, amputation was performed by me through the knee-joint. Seven months after removal of his limb he was re-admitted presenting a remarkable appearance as represented in the drawing taken of the head and face. When seen during the interval he was stout, hale, and strong, which was recorded in a photograph he had had taken of himself; now his body is wasted, face elongated, head enlarged, showing three elevated bosses distinct from one another, separated by deep furrows consisting of a firm and even enlargement. The left eyeball protruded, double its normal size, lips heavy and corrugated. The stump is free from any recurrence, as also the femur, but enlargements, tumefied and nodulated, were to be felt along the spine. The growths on the outside and within the head increased, and within four months death supervened.

The case represents the rapid diffusion of sarcomatous disease.

I show you to-day a sarcomatous breast which I recently removed from a woman, æt. 72. The growth encircled the axillary vein, and filled up the axilla. This seemed by the history to be where the disease first formed. A second tumour developed in the breast. These, as you may see, are encapsuled and are distinct and well separated from one another. She has made a good recovery.

I show you a specimen of cystic sarcoma of the right ovary; it weighs, taken the following morning after removal, 8 lbs. Its circumference, measured at its greatest diameter, 26½ ins., at its least, 18 ins., taken from a single woman, æt. 52, well nourished, with a history of from five to six years' growth. She naturally was very incommoded by it, and was unable to lie flat on account of the dyspnoea it produced. There was present a good deal of ascitic fluid in the peritoneum. She made a good recovery and was discharged.

Perhaps the most remarkable case of sarcoma of the liver is a specimen I show you. I explored it during life, and it was removed at the post-mortem. No metastasis was found elsewhere. It weighs 19½ lbs.

The secondary operations for recurrences of

sarcoma are by no means favourable, for as I have said, the disease spreads by the capillary system and gets diffused at a rapid and early date, and is more fatal than carcinoma.

I show you now some scirrhus cases of the breast, the disease is held for sometime local, and if it spreads by the lymphatic system, the lymphatic glands check for a time its further advance. Mr. Harold Stiles, (*Edinburgh Medical Journal*, 1892) in his paper demonstrates that the lymphatics of the breast extend from the mammary gland first into the pectoral fascia, and often into the pectoral muscles, and pass from thence into the axillary glands, and this, Heidenheim says, "although apparently the disease might be limited to a spot quite remote from the muscle."

I have seen surgeons remove a cancerous nodule in the breast and leaving the breast, with the result of early recurrence, necessitating a very extensive (Stiles's method) operation. In one case I performed the second operation, hoping for good results, eight months after the first, well clearing out the axilla. Six months after this second operation glands in the axilla developed. These I removed, as also some above the clavicle. She recovered with good movement in her arm, and has remained without recurrence. (I may just mention I dress all my breast cases with the arm held out at right angle to the trunk, when in bed slinging the arm to the head of the bed to make it keep in that position; after three weeks a patient can have perfect control, and even dress her own hair.)

Malignant disease, wherever situated, is much more likely to recur in persons under thirty or thirty-five than it is in people over fifty. Although the disease may return *in situ* or in the lymphatic glands, yet by removing them again and even again, ultimately it may be eradicated. I have operated thirteen times on the same lady, extending over several years; this with others demonstrates the absolute necessity of patients being advised to submit to repeated operation, and taking the precaution of their presenting themselves for examination frequently, at least every three months, for three to four years after the breast has been removed, and should a nodule be discovered, its removal by operation should at once be undertaken.

I have a case just left the hospital whose right breast was removed for cancer four years ago. That side is perfect. She presented herself with a scirrhus tumour in the left breast on which I operated freely. Undoubtedly she was cured of her first attack, and we must consider the formation of a scirrhus tumour in the left not as a recurrence but as a fresh outbreak of a local attack coming on in a woman predisposed to cancer. She has made a good recovery, and a favourable prognosis may be anticipated.

A tumour forming in the breast of a female, or a male, after the age of forty to forty-five, may be confidently assumed as of a malignant character and dealt with accordingly with the hope of a good recovery, but in patients under thirty-five, prognosis is considerably worse than in the older patient and those who have passed the menopause.

One word with respect to those cases of malignant disease of the breast in which operation is not admissible, or in cases of recurrence that have taken place and no further removal can be undertaken. In these cases Dr. Beatson has advocated double oöphorectomy, and has urged strong arguments in favour of his theory. Mr. Stanley Boyd has given the treatment a fair trial, and has published his results, but I fear the results must be yet put down as not proven; both Mr. Jessett and myself have done oöphorectomy for inoperable cases of carci-

noma of the breast, and we both have seen no benefit resulting; indeed, in one case I found both ovaries cancerous. The idea is ingenious and fascinating, but from the cases I have read and my experience so far, I would not advise the procedure.

Let us turn for a few moments to carcinoma of the uterus. There are several specimens before you. The same rule holds good here as in cancer of the breast. The younger the patient the worse is the prognosis. Early diagnosis is of the utmost importance; malignant disease detected early can be operated on with every hope of success. Vaginal hysterectomy is not a dangerous operation. As to prognosis after operation, much depends on the position of the disease, the extent of it, and the length of time it has existed.

I may impress the necessity of making a good and thorough examination, under an anæsthetic, if necessary. The object is to find out the extent the disease has spread. This can be determined by the conjoint examination per vaginam and per rectum, with the left hand above the pubes.

My first case of vaginal hysterectomy I published in the *Lancet* of January 31st, 1885, page 200. She was operated on on September 23rd, 1884, and she made a good recovery. I acknowledge that this, the first case performed, was a fluke, for I did not start with the object in view. She had a papillomatous growth, about the size of a cricket ball, filling up the vagina, attached to the os and left vaginal wall, being excessively vascular. The growth was removed by means of the galvanic wire écraseur without loss of blood. While examining the charred stump I found I had opened the peritoneum into Douglas's pouch. I decided the only chance of the patient being freed of the disease was to extirpate the whole organ. With the consent of my colleagues I proceeded to do so. One ovary which was cystic was removed; the other appearing healthy was left.

Other cases followed, and my fourth was a historical one. It was a challenge case from the late Mr. Lawson Tait, sent up from the Birmingham Hospital for Women. Dr. John W. Taylor, of Birmingham, represented Mr. Lawson Tait; others were present, including Mr. Henry A. Reeves, as also my colleagues, Snow and Jessett. I acknowledge this was a test case as to the feasibility of the operation of vaginal hysterectomy. It was performed on June 23rd, 1887, at the Cancer Hospital, and report was published in the *Lancet*, August 27th, 1887, p. 411. The woman made a good recovery, and after this vaginal hysterectomy became an established and recognised operation. I firmly believe if my first six cases had not been successful, the operation of vaginal hysterectomy, so far as England was concerned, would for years have been tabooed. The Cancer Hospital may be proud to be the pioneer of an operation that has given signal relief and cure to many. The operation has been performed here in over 300 cases, and the mortality which in the early series was 17 per cent., is now brought down to 2 per cent. and 3 per cent. This low mortality is accounted for by the better selection of cases. English surgeons and gynecologists can now furnish series of cases by the hundred, yet few may remember or even know of the pioneer cases. Like every other new departure it had to fight its way to the front, which it has done successfully. I would never recommend the performance of vaginal hysterectomy without explaining and impressing the risks of the operation to the patient and her friends.

University of Birmingham.—Faculty of Medicine.

The following candidate has passed Parts I. and II., Examination for the Diploma in Public Health:—Thomas Edward Dyson.

A CASE OF TRAUMATIC FUNCTIONAL PARALYSIS. (a)

By MARTIN DEMPSEY, F.R.C.P.I.,

Assistant Physician, Mater Misericordiae Hospital.

J. M., a boy, *æt.* about 12, fell from a wall to the ground, a considerable distance, alighting on his right shoulder-joint. He did not appear to suffer much at the time; but the following day he was punished for not writing his copy as well as usual, and it was noticed not long afterwards that the boy had lost the power of his right arm, which hung powerless by his side, with the terminal joints of his fingers slightly flexed. The shoulder-joint was X-rayed, and an anodyne liniment rubbed to the joint for months without benefit. The limb was distinctly wasted, he was unable to move it, the least touch above the elbow and as far as the shoulder gave him excruciating pain, though a blow on the part or pressing the flesh with a pencil drawn over it caused no sensation. Pins might be stuck deeply into the flesh of the upper arm, over the region of the scapula without his being conscious of the act. He felt the sensation of cold when a test tube with cold water was placed on the skin; but the application in the same way of warm water was unrecognised. Under the influence of the Faradic current the muscle tissue reacted energetically. For two months the faradisation of the muscles has been continued with distinct benefit to the boy.

With the exception of this muscular wasting, no other trophic disturbance was noted.

Examination of the reflexes yielded no satisfactory result.

On testing sensation it was found that over the great part of the limb (the exact area shall be mentioned later) the lightest touch of the finger could be felt, but the hardest stroke with a bluntly-pointed lead pencil was unnoticed, even when the pressure was severe enough to move not only the arm but the whole trunk. A pin stuck into the skin produced no sensation, and curiously enough, though cold water in a test tube was invariably identified when brought into contact with the skin, hot water similarly applied was not felt at all. The area over which this dissociation of sensations existed embraced the whole arm, with the exception of the back of the hand and over the pectoral and scapular regions for about two inches. Sensation was perfectly normal on the back of the hand.

The muscles reacted briskly to the Faradic current.

As regards the diagnosis, my first impression on seeing it and hearing the history of injury was that I was dealing with a case of traumatic brachial neuritis. I may say that I thought at the time that the paralysis had immediately followed the injury. On carefully mapping out the areas of sensory disturbance and finding they failed to correspond to the areas of skin supplied by the nerves of the arm, I commenced to doubt the accuracy of this opinion, a doubt strengthened later by the discovery that the muscles, which were absolutely paralysed, and had been so for over two months, reacted normally to the Faradic current. Of the other two views which occurred to me as possible cause the first, an intraspinal hæmorrhage pressing on the nerve roots was rejected for the same reasons; and the second, a hæmorrhage into the grey matter, was untenable for the following reasons:—(a) The sensory disturbance did not conform in its distribution to the areas of the skin in connection with the segments of the cord, which would of necessity have been damaged in order to produce the motor paralysis; (b) retention of Faradic continuity in the paralysed muscles; (c) the absolutely monophyseal character of the paralysis.

Thus finding it impossible to reconcile the conditions present with an injury to the nerves, nerve links or cord, I was thrown back on what seemed to me the only possible explanation—*viz.*, to regard the case as one of functional or hysterical paralysis. The correctness of

this view is, I think, borne out by the subsequent course of the case, which I may now relate.

Two weeks after admission the hyperæsthesia of the upper arm completely disappeared and sensation returned in the arm as high as the elbow. Above this joint the skin still showed the peculiar sensory phenomena. There was also some increase of power in fingers and hands.

Week by week power increased, first in the arm and finally in the shoulder, and at present the boy has very fair power in the whole limb.

The sensory disturbance in the upper arm persisted, but showed variation in extent, some days invading the pectoral area as far as the middle line, at other times being barely perceptible on the chest.

To-day, after a brisk faradisation, sensation was perfectly normal.

It is interesting to note the close resemblance of the sensory disturbance to those seen in syringomyelia, and this seems to me to suggest the possibility that some at least of hysterical phenomena may be due to functional derangement of the cord and not of the brain.

Clinical Records.

A CASE OF RECURRENT PAPILLOMA OF THE VAGINA. (a)

By W. WALTER, F.R.C.S.I.,

Hon. Physician to St. Mary's Hospital for Women and Children, Manchester.

THE patient, *æt.* 37, and unmarried, was admitted into St. Mary's Hospital in August 1898, complaining of bleeding from the vagina between the periods, which had continued off and on for several months. Her general condition was good. The uterus and other pelvic organs were healthy. Inside the vagina on the posterior wall, was a small papilloma which bled readily. This was curetted and the thermo-cautery applied freely. The microscopic character of the scrapings presented the appearance of a simple papilloma with no sign of malignancy. In November, 1898, the patient re-entered the hospital, as the papilloma was commencing to recur. The cautery was again applied. The following year on two occasions a similar treatment was necessary.

In 1900 the patient was readmitted in June and December. The patches were larger in size than formerly, but still quite superficial and free from any deep-seated attachment. The cautery was applied to the affected surface.

Last year, in March, July, October and December, the patches had returned, and were spreading upwards on the posterior and left wall. In December it was found that infiltration into the perivaginal tissue on the posterior and left side had occurred since her previous visit. As the vagina was extremely narrow the perineum was divided and the part exposed to view. A patch of mucous membrane the size of a shilling, with a raised and granulating surface, together with a small growth nearly as large as a filbert nut were removed, and the vagina packed with gauze.

"The microscopical appearance of the growth shows a fibrous and elastic tissue matrix containing a considerable number of cell nests."

A CASE OF TRADE ECZEMA. (b)

By ARTHUR J. HALL, M.B., M.R.C.P.,

Physician to the Royal General Hospital, Sheffield.

THIS case is of eleven years' duration. The eruption affects the hands and arms. The patient, a female, is a polisher who works in Tonge. She was shown to the Society on a previous occasion, and since then has been applying calamine gelatin daily over the dorsa of fingers, hands, and forearms, with the result that she had been perfectly free from eczema for several weeks. A few days ago a very interesting thing occurred.

(a) Paper read at the North of England Obstetrical and Gynaecological Society, January 17th, 1902.

(b) Patient shown at meeting of Sheffield Medico-Chirurgical Society, January 16th, 1902.

(a) Read before the Royal Academy of Medicine in Ireland, Jan. 24th, 1902.

She got an outbreak on the dorsa of fingers and knuckles of right hand. This is the part which the rouge affects most, and where the gelatin is more likely to be rubbed off or undermined. But the patient was menstruating when this attack began, and her mother assures me that she is always worse in the hands at those times. We see then, in this case, the possibility that the skin reflex may be more irritable during the menstrual period, and be irritated then by a weaker irritant. But this fact is one that is common to all eczemas—who has not seen the eczema of pregnancy, or lactation, or the eczema of chlorosis, or even the eczema of "mental worry"? If that is so we have a further argument for the theory that many of these cases of so-called trade dermatitis agree with cases of eczema in that they are worse in various constitutional states of the individual. The more I see of these cases, the more do I see a difficulty in drawing any line between many of the trade affections (dermatitis) in which the irritant is known and can be avoided, and the eczemas in which the irritant is not known (?) and cannot be avoided (?)

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.
MEETING IN THE ROYAL COLLEGE OF PHYSICIANS,
ON FRIDAY, JAN. 24TH, 1902.

DR. HAWTREY BENSON in the Chair.

DR. MARTIN DEMPSEY exhibited a Case of Traumatic Functional Paralysis.

Dr. J. J. BURGESS then read the report furnished to him by Dr. McWeeney, of the histological examination of the heart he exhibited at the last meeting. (1) Intense and uniformly distributed fibrinous pericarditis; non-tuberculous. (2) Extreme fatty infiltration of the anterior wall of the right ventricle. The nature of the material was readily demonstrated with osmic acid and audiu III. There is not the faintest indication of tumour formation. (3) A moderate amount of sclerosis of the coronary arteries, with thrombosis of the descending branches of one of them. (4) The source of the hæmorrhage was not ascertained.

Dr. J. M. DAY then read his paper on

THE DIAGNOSIS OF SCARLATINA.

The diagnosis of scarlatina has now become a far more difficult matter than formerly, when the disease was of a severer and better marked type. The chief symptoms of scarlatina are vomiting, sore throat, elevation of temperature, frequent pulse and a rash. If scarlatina be present the red punctiform appearance on the pharynx, soft palate, tonsils, and hard palate will be found. The pulse rate is quick, even in the mildest cases. The rash is never seen in the circum-oral zone. The skin is dry, but sweating may occur in rheumatic subjects. When the disease is accompanied by gastric catarrh the tongue is furred. Scarlatina may occur a second time *sine eruptione*. Desquamation may commence on the sixth day, or be delayed until the twenty-first day. It spreads centrifugally from points. Scarlatina may be confounded with röteln, measles, septicæmia, urticaria, erythema, rheumatic fever, meningitis, enteric fever, and drug-rashes. Scarlatina, being a fixed disease, is seldom or never contracted twice. [We hope to publish this paper in full in our next.]

Dr. DRURY recognised the difficulty in diagnosis of scarlatina, and the importance of a correct diagnosis, as many unpleasant results may follow on a mistake. Long confinement to bed may of itself produce desquamation; if the person is accustomed to a daily bath you may get almost no desquamation. Polishing of the finger nails may escape observation.

Dr. POLLOCK had two anomalous cases: (1) Bad vomiting, sore throat, no rash; on the tenth day he found some rash and desquamation. Six months afterwards the patient got a severe attack of scarlatina with

otorrhœa, and died. The second case was marked by a sore throat, punctiform rash of palate, bleeding of mucous membrane of mouth, and inflammation of throat. Seventh day the case proved to be one of gastric fever.

Dr. HAYES found the difficulty of diagnosis of scarlatina most in adults. In mild cases there was no constitutional disturbance, the typical scarlatina throat may be absent. He principally based his diagnosis on the punctiform rash of the hard and soft palate and the rapid pulse. Temperature was of little diagnostic value, desquamation not easy of recognition in every case. He thinks there is a certain relation between the extent of the rash and the amount of desquamation.

Dr. CRAIG was glad to hear such a practical paper. He isolates all doubtful cases, the author did not include the rash of influenza in his list, it is not unfrequently followed by desquamation. Surgical scarlatina due to septic causes may be recognised by the absence of sore throat and the rash not extending to the face.

Dr. DOYLE found the rash of belladonna to closely simulate scarlatina. He thinks that patients are sometimes sent out of fever hospitals without being medically examined before their discharge, which is wrong. Such a case came under his notice. The child was dismissed on a Tuesday, and on the following Thursday had the scarlatina rash on its body.

Dr. MORE O'FARRELL would like to know from Dr. DAY the incubation period of scarlatina, and the exact cause of scarlatina? Does Dr. DAY examine the blood of scarlatina patients—it is done in Vienna? He has observed that scarlatina conveyed by milk is always of a mild type. He had two cases, one of which was under conditions for a week in which it was impossible that infection could be conveyed to her, and yet she got scarlatina. In the second case the patient's environment scarcely admitted of infection for a full month, yet she took it. He has seen cases of an outbreak of scarlatina in a family, and found that the dark-haired persons were those who took the fever, the light-haired ones escaping. Dark-haired persons suffer more than fair-haired when attacked.

Dr. HEAD thought desquamation may be deferred for a longer period than twenty-one days. He told of a series of cases in which desquamation was deferred for a month. Patients should be kept a longer time in hospital. He found a rash following on influenza to closely simulate scarlatina. In the fourth disease the skin peels in large patches.

Dr. BYRNE found that röteln is only found when scarlatina is epidemic.

Dr. DAY considered that there was a certain proportion between the amount of the sickness and the rash. He was not inclined to extend the period of desquamation beyond twenty-one days. Hebrew children have a dark rash on the first day. He quite agreed with Dr. Hayes respecting adults. He did not know any surgical scarlatina. There may be septicæmia with a rash, or a surgical patient may contract scarlatina. No patient can leave hospital until examined by the physician. To find the exact cause of scarlatina he leaves to Dr. O'Farrell's industry. The period of incubation, he thought, was generally known—it is eight days. The mildness or otherwise of milk conveyed scarlatina is dependent on the character of the epidemic. The infection is not so much due to the desquamation as was formerly thought. Any discharge, otorrhœa, may convey infection. Does not place reliance on the observation of nurses—observes for himself. He looks on the fourth disease as non-existent, being no more than a form of röteln.

Dr. MARTIN DEMPSEY brought forward a case of
TRAUMATIC FUNCTIONAL PARALYSIS.

A boy, æt. about 12, fell from a height a considerable distance on his right shoulder-joint. The case will be found reported in another column.

Dr. CRAIG agreed with Dr. M. Dempsey in his diagnosis. He had had a somewhat similar case in a girl.

Dr. LANGTON SYME saw many cases of functional diseases in the Great Ormond Street Hospital. By throwing them off their guard you usually succeed in

your diagnosis. All the cases he saw were in boys, and he found them associated with phymosis. Dr. Dempsey's patient had a long foreskin.

Dr. GOULDING asked was there any history of a sore throat?

Dr. DEMPSEY having replied, the meeting terminated.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JAN. 15TH, 1902.

Prof. T. B. FRASER, President, in the Chair.

Dr. BYRON BRAMWELL showed two cases of syringomyelia. (1) A young man, *æt.* 17, who had atrophy of the small muscles of the hand leading to claw-hand, with evidence of paralysis of the sympathetic on the same side, as shown by narrowing of the palpebral fissure, contraction of the pupil, flattening of the side of the face, and recession of the eyeball as a whole. Such a combination—paralysis of the cervical sympathetic, with wasting of the hand muscles—was practically pathognomonic of syringomyelia. The duration in this case was about a year; there was no affection of the sensation of touch or pain, but thermal sensibility was disturbed over the left area and adjacent parts. The reflexes in the leg were exaggerated; there was ankle clonus and an extensor plantar response. The patient was short, and rather broad for his height, a configuration which had been noted in many cases of the disease. (2) A female, *æt.* 30, who had suffered for some time from recurring sores on the hands and feet, either developing spontaneously or after slight injury. This patient showed wasting of the biceps and muscles of the left shoulder girdle, inequality of the pupils, exaggeration of the deep reflexes, and dissociated anesthesia, thermal sensibility being entirely absent over the upper part of the body.

Mr. H. J. STILES showed (1) a boy after punctured wound (spike of railing) of brachial artery opposite the origin of its superior profunda branch, treated by ligation of the proximal and distal ends of the main trunk and of the proximal end of the profunda, without there being any interference with the circulation in the arm. (2) A girl after excision (second operation) of plexiform angioma of scalp. As related at the Society a few months ago a preliminary ligation of the feeding arteries was performed, but as the subsequent electrolysis had no effect excision was determined on. The dissection out of the vessels had been very difficult, and was attended by free hæmorrhage, which was controlled by sutures round the edge of the wound, and the application of peroxide of hydrogen to the smaller vessels.

Dr. WM. ELDER showed a case of complete transposition of the viscera.

Dr. MACGILLIVRAY showed a case of obstruction of the bowels in a child with suppurating tuberculous retro-peritoneal gland, on whom he had operated successfully. The child was *æt.* 4½, and had suffered from abdominal pain since she was a year old. Complete obstruction set in on November 27th, and she was admitted to hospital with fecal vomiting on December 3rd. The abdomen was greatly distended, and on opening it, the obstruction was found to be due to bands of fibrous tissue constricting the bowel near the ileo-cæcal valve. These, along with a mass of tuberculous glands the size of a tangerine orange lying behind them, were removed, and the patient recovered.

Dr. LESLIE MACKENZIE showed a simple form of spray pump for disinfection. It weighed only 8 lbs., and so could easily be carried about by a sanitary inspector, and was designed especially for small towns and for hospitals for which the regulation spray pump was too large.

Dr. CHALMERS WATSON showed photographs of a case of cerebral thrombosis in a horse, followed by complete recovery.

The following card specimens were shown:—By Mr. STILES: 1. Portion of brachial artery from patient exhibited. 2. Congenital strangulated cyst, weighing 1½ lbs., removed, along with six inches of small intestine,

from a child, *æt.* 29 months, who was suffering from obstruction.

By Dr. BRUCE: Transverse section of aortic aneurysm.

By Mr. J. M. COTTEILL: 1. Pouches and sac removed in a case of intra-peritoneal rupture of a tubal gestation. 2. Aneurysm of the posterior ulnar recurrent artery. 3. Semilunar cartilage from a series of cases of internal derangement of the knee-joint. 4. Specimens from a case of fracture of the sternum and dislocation of the spine. 5. Kidney removed on account of profuse hæmaturia.

By Dr. MACGILLIVRAY: Large papilloma of rectum.

By Drs. GIBSON and MACDONALD: 1. Spinal cord, showing pseudo-tubercles syphilitica. 2. Hæmorrhage into the cusps of the semilunar valve.

Mr. C. W. CATHCART demonstrated an adaptation by Dr. Ramsay Smith of the freezing microtome for tropical climates, and of his rapid method of mounting permanent microscopical sections of fresh tumours. Full details of the method will be found in Dr. Ramsay Smith's paper in the *Scottish Medical and Surgical Journal* for January, but its main features are as follows:—To adapt the freezing method to very hot climates the tissue is imbedded in cork, and frozen by spraying directly upon it with chloride of ethyl; in this country Mr. Cathcart found that ether acted equally well. Cutting is done by moving the tissue continuously upward, no attempt being made to adapt the movement to each cut. Fresh tissues are mounted as permanent specimens by floating out the sections in 2-4 per cent. formalin after they are cut. They are then stained, dehydrated, and cleared on the slide, and mounted on balsam. Dr. Smith can by this method cut 300 to 400 sections per minute, and can produce a completely stained permanent specimen in six or seven minutes after receiving a specimen from the operating theatre.

TUMOUR OF PRE-FRONTAL LOBE.

Dr. W. ELDER and Mr. A. MILES read notes of a case of tumour of the pre-frontal lobe successfully treated by operation, which will be found on page 131.

In discussing this paper Dr. BRAMWELL said that his experience confirmed that of Dr. Elder, that very few cerebral tumours benefited by operation, indeed he himself remembered only one case which was successful. Three years ago he had reported eleven cases of frontal tumour, in seven there were mental symptoms, in four none. He thought that it would be almost impossible to draw a distinction between certain cases of general paralysis and some frontal tumours; it was impossible to say how far the mental symptoms were due to pressure on the frontal lobes, and how far to pressure on other parts of the brain, and it must be remembered that lesions diffused over the cortex would often produce symptoms very similar to those of perforated tumour.

Dr. EDWIN BRAMWELL referred to the frequency with which pain in the back was met with in central tumour.

Dr. BRUCE suggested that this might be due to pressure on the nerve roots by accumulation of cerebrospinal fluid; in many cases of cerebral tumour degeneration of these roots was present.

Mr. Cotterill, Dr. Logan Moore, and Dr. Church also spoke.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD JAN. 16TH, 1902.

The President, Dr. C. H. WILLEY, in the Chair.

Dr. SINCLAIR WHITE exhibited:—1. Phosphatic calculi and prostatic tissue removed supra-pubically from a patient, *æt.* 63, who had been suffering from enlarged prostate. 2. An excised gastric ulcer removed from the anterior wall of the stomach of a man, *æt.* 24. The ulcer had existed for two years, and had perforated eighteen months previously, but owing to extensive adhesions the general peritoneum had not been found. The ulcer was about one inch in diameter, and funnel-shaped. The walls of stomach around the ulcer were fully one-third of an inch in thickness, and a dense band of fibrous

tissue united the ulcerated area to the anterior abdominal wall. The patient was now quite free from his old symptoms. 3. A child, *et.* 2, the subject of extroversion of the bladder, in whom the ureters had been transplanted into the rectum by the extra-peritoneal method described by Dr. Peters, of Canada. Peters' operation was described and criticised.

Dr. ARTHUR HALL showed (1) a case of "Acute Myelitis," in which the first lesion had occurred in the lower thoracic region of the cord, accompanied by marked pyrexia, diarrhoea, and vomiting. It was an incomplete one, the left side of the cord being more affected than the other. An interesting feature of this first attack was the presence of a circular ring of acute bedsores, due to the pressure of the rim of a chamber-pot on which the patient had been placed before admission for some hours on account of his diarrhoea. About five days after his first attack, the patient began with symptoms of paralysis in both arms, dysphagia, paralysis of the tongue, and became temporarily insane. These symptoms lasted about a week, and seemed to form a true relapse, with possibly lesions in the brain as well as the upper cord. The patient made a complete recovery. (2) A case of "Occupation Neurosis." A single man, *et.* 43, a brick-layer, had for two years noticed loss of power in the right hand, varying from time to time. It is most marked when using his trowel. The hand goes quite numb, and sometimes gets stiff and straight. He gets marked tremors and pain in it if he gets excited. It followed influenza two years ago. He lives alone with a widowed mother, and saw his father killed by a fall from a scaffold five years ago. These points are mentioned to show the nervous character of the case. He finds that after a glass of beer his hand gets better; also, he can check it by a rubber ring on the finger; these facts again showing the psychical element in the condition.

Dr. HALL also showed a case of "Trade Eczema." The history of the patient will be found under "Clinical Records."

Dr. WILKINSON related "Two Cases of Successful Operation for Ruptured Intestine." Case 1: A boy, *et.* 12, was stabbed in the lower part of the abdomen with a pocket knife. The intestine was wounded in two places, and the mesentery in one. There was much bleeding and some extravasation of faeces. Resection of the wounded portion of intestine was performed, and the ends united over a Mayo-Robson four bobbin. Case 2: A boy, *et.* 11, was kicked in the abdomen by a horse. Dr. Wilkinson saw him twenty-four hours later, when signs of acute general peritonitis were present. The abdomen was opened by an eight inch incision in the middle line. A circular hole half an inch in diameter was found in the ileum and sutured. A large faecal collection was found in the lower part of the abdomen, and general septic peritonitis was present. After wiping out the extravasated faecal matter, evisceration and thorough irrigation of the abdomen was performed. The abdomen was closed without drainage. Though much collapsed after the operation, the patient eventually made a good recovery.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

ANNUAL MEETING HELD AT MANCHESTER, FRIDAY, JAN. 17TH, 1902.

The President, S. BUCKLEY, M.D., in the Chair.

Dr. A. DONALD (Manchester) exhibited two specimens of Tubal Mole. In each case the occurrence of hæmorrhage at about the sixth week had destroyed the life of the ovum without leading to rupture of the tube. Each tube contained a mass of clot embedding an embryo surrounded by its amnion but with no trace of liquor amnii. No blood or clot was found in the peritoneal cavity. In one case amenorrhœa for nearly two months had existed; in the other the menstrual period had not been missed. In both the bleeding was profuse and lasted for six weeks, and a well-defined tumour was felt on one side of the uterus. The tubes were

removed by abdominal section in the first case and by anterior vaginal section in the second. Both patients made a good recovery.

Dr. A. DONALD and Dr. W. E. FOTHERGILL (Manchester) showed sections from a case of Folliculoma Ovarii Malignum. The tumour about the size of a cocoa-nut, was hard, solid and nodular. It was removed from a single woman, *et.* 57. The clinical features of the case suggested malignancy. There were wasting pain and ascites. The sections showed the growth to consist of alveoli filled with epithelial cells and embedded in a fibrous stroma. The alveoli varied in size and some of them contained one or more large cells presenting the characters of egg-cells in various stages of development.

Dr. W. E. FOTHERGILL (Manchester), showed a Series of Sections of Uterine Casts from Cases of Membranous Dysmenorrhœa. The casts were all shown to be composed of fibrin and leucocytes. Dr. Fothergill had examined many such casts and had never found any composed of mucœa with a lined cavity such as are frequently described.

Dr. J. B. HELLIER (Leeds), showed an Early Ruptured Tubal Gestation. The patient, *et.* 35, married eleven years, had one doubtful abortion some years ago. She did not suspect pregnancy and menstruation was quite regular. While cycling she was seized with sudden abdominal pain and faintness. Internal hæmorrhage was suspected and abdominal section was performed. Much dark blood-clot was found in the peritoneum. A very small tubal pregnancy had caused rupture of the right Fallopian tube, which was removed. The patient made a good recovery.

Dr. W. WALTER (Manchester) showed a specimen of Fibro-myoma of the Uterus removed from a single woman, *et.* 39, by abdominal hysterectomy. The patient had suffered from pain and hæmorrhage for some time, and for eight months was unable to follow her occupation at the mill. On January 14th abdominal section was performed, the broad ligaments tied and divided in the usual way and the uterus removed by a wedge-shaped incision just above the vaginal roof. The cervix was dilated from above downwards with a pair of Spencer Wells' small forceps, and a narrow gauze drain passed down into the vagina. The ligatures were cut short, and the peritoneum stitched over the stump except at a small spot where the end of the gauze served as a drain. The abdominal wall was closed with silk-worm-gut sutures, and in addition buried catgut was used for the muscle and fascia. The specimen removed consisting of a sub-mucous fibroid springing from the fundus and anterior wall of the uterus was undergoing in some parts myxomatous degeneration, and in other fatty degeneration. The patient was progressing so far favourably, but without including this case Dr. Walter had just completed a series of thirty-five abdominal hysterectomies for myoma with one death.

Dr. WALTER also brought forward a case of

RECURRENT PAPILLOMA OF THE VAGINA, which will be found under the heading of "Clinical Records."

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 1st, 1902.

At the Society für Innere Medizin, Hr. Ziegenhagen presented a case of

AORTIC ANEURYSM RUPTURING INTO THE VENA CAVA.

The patient, a man, *et.* 73, an office clerk, was admitted into hospital in April of last year. The chief symptoms were an indescribable cyanosis, and the want of relation between the upper and lower halves of the body. The former was swollen, with extreme œdema, and the latter normal. There was great dyspnoea, and the pulse was rapid. On examination, great enlarge-

ment of the left ventricle was found, absolute dulness below the right clavicle, at the cardiac apex, and above it a loud systolic sound and a systolic murmur over the sternum. There was no difference in the pupils of the two sides, or of the radial pulses, and there was distension of the veins of the thorax. The diagnosis made was aneurysm of the aorta, with compression of the vena cava. Compression of the vein, rather than rupture of it, was assumed, as the history was not in favour of the latter. The patient stated that since 1900 he had had tightness of the chest, which gradually increased in intensity, so that from April 1st he had to keep his bed. The oedema of the upper half and the cyanosis had come on gradually without any noticeable onset, whilst in other cases of rupture into the vena cava the contrast between fair health and the sudden onset of fatal symptoms was well marked. The patient died two days later during sleep without any further special development of symptoms. Section showed a large tense tumour in the right half of the thorax adherent to the pleura and vena cava and communicating with the latter by an opening admitting a lead pencil. It was quite clear that the rupture had taken place before the patient's admission into hospital, as none of the violent symptoms, usually accompanying it, were observed during the time of his stay therein.

Hr. Kammer gave a preliminary report on
TOXEMIA.

For some years he had been making investigations at first at the Third Medical Klinik and later at the Polyklinik for chest diseases. They were not yet completed, but they had led to important results. They were in regard to Ehrlich's iodine reaction on leucocytes, of which three stages were distinguished—(1) Diffuse red staining of the protoplasm contrasting with the white nucleus; (2) red-brown granulation of the protoplasm; (3) almost complete conversion of the protoplasm into red-brown granules and flakes (very rare). Ehrlich, who first found the reaction in the blood of a diabetic, took the red-coloured substance for glycogen. Then the reaction had been described by various authors on infectious diseases, in cachetic leucocytosis, in aseptic suppurations, and by himself as constant in puerperal fever. But up to the present there had been no law and no standard. It had struck the speaker that the iodine reaction was present in almost all cases in which bacteria were present, actually or potentially. In consequence of this he had studied the influence of the various bacterial cultures on the iodine reaction in guinea-pigs and rabbits. The normal leucocyte of these animals was indifferent as regarded iodine. He first injected a virulent streptococcus bouillon culture intravenously into a rabbit. In eight hours appeared the first trace of iodine reaction, and this developed within twenty-four hours to the third stage. In a similar manner the reaction was brought about by virulent bouillon cultures of streptococci, staphylococci, pneumococci, diphtheria bacilli, typhoid bacilli, Friedlander's bacilli, anthrax bacilli, bacilli pyocyaneus, bacterium coli, but not by the bacilli of fowl cholera. He had then filtered the bacilli to sterility, and the filtrate and the toxin he had injected into animals, likewise with prompt positive results. The reaction could not be obtained with tetanus toxines. Here was possible a cross light on the

difference between actions of tetanus toxin and diphtheria poison. The next question was, if this reaction were produced by toxines, what rôle did the antitoxines play in it? He had never seen the reaction in highly immunised animals. It appeared to be proved that a reaction specific for the diphtheria poison would be prevented by the injection of a specific antitoxin.

In the case of the chronic infectious diseases, such as glanders, tuberculosis and *perlsucht*, there was a striking divergence. The reaction could not be produced by subcutaneous and intravenous injections, but it could by feeding with the bacilli of glanders—tubercle and intraperitoneal injection of all the three kinds of bacilli, but only after the lapse of twelve days.

In the human subject the reaction could only be determined when toxines or bacteria were present in the system in sufficient quantity to produce an effect. The reaction could therefore be of service both from the point of view of differential diagnosis and of indication.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Feb. 1st, 1902

CICATRICES FROM CAUSTIC POTASH.

TELEKY showed the preparation of an œsophagus taken from a young ironworker, æt. 22, who drank a quantity of caustic potash by mistake two years before his death. The stricture resulting from the cicatrix gradually increased until even small quantities of fluids could only be swallowed with difficulty. In 1900 he came to the polyclinic in great distress, with a small piece of meat sticking in his gullet, which he could neither get up nor down. The passage of bougies did not assist matters, and finally gastrostomy was performed. He was recovering rapidly from the operation, when death suddenly supervened, and the post-mortem examination revealed the fact that 10 centimetres of the œsophagus had undergone carcinomatous degeneration at a part immediately behind the bifurcation of the bronchial tube, which is a very unusual position, particularly at this age, of which we have only other three on record to refer to.

The second case was that of a young woman, æt. 38 who had taken caustic potash when six years of age. After recovery from the injury the patient was quite unable to swallow meat. The bougie showed that upwards of 20 centimetres of the œsophagus was the seat of a hard stricture. By the constant use of bougies and laminaria tents the calibre was increased to 9 millimetres in six months; but although the treatment was continued for more than another six months, it had no further beneficial effect. At this time Hebra had been using thiosinamin for softening cicatrices with excellent results. Teleky then used ten injections in four weeks of a 10 per cent. alcoholic solution over the spine. The application of the bougie was recommenced, and although a No. 4 could be passed with difficulty, in a short time three numbers higher could be passed with ease, till now she can swallow meat freely without the least trouble.

With Hunzel's œsophagoscope the old stricture can be seen with fine concentric rings of a reddish grey colour, with fine perforations in the elastic tissue.

In a third case a child had swallowed caustic potash

and produced a stricture which had been treated with thiosinamin for four weeks with the result that a stricture of $9\frac{1}{2}$ millimetres could be dilated to $12\frac{1}{2}$ m.m.

On the other hand, he related the case of a child, *et.* $3\frac{1}{2}$, who had been treated with thiosinamin with apparent improvement at the beginning, but for some reason not yet clear, the condition retrogressed rapidly, and the little patient was soon as bad as at the commencement of the treatment. Gastrostomy and a conical tube had to be resorted to in this case.

It may be noted here that the first case was also treated with the thiosinamin solution after the gastrostomy was performed with apparently good effects at first, but the carcinoma which had taken origin in the oesophagus and subsequently penetrated the bronchus, brought the case to a sudden termination through gangrene of the lung.

We may conclude that the drug is efficacious in normal tissues in facilitating the dilatation of the elastic tissue of cicatrices, and that in a recent cicatrix, of say six to eight weeks' standing, it produces nerve tissue by swelling and retracting.

It should be used cautiously, and never when there is inflammation in the cicatrix, as apicitis is a sure index of pending danger. During the administration of the drug for a cicatrix of the oesophagus the stretching can be accomplished by the bolus, although a bougie may often be used with advantage; but when we consider Hackner's statistics, that the mortality of bougie cases is 55 per cent., which has been confirmed by others, it might be more prudent to abstain from the bougie and watch the effect of the drug.

Neumann regretted that Hebra was not able to be present, through illness, to give a personal report of his success with this drug. Neisser used it last year in scleroderma with considerable success. Neumann concluded with a promise to bring some cases before the society in which he had made use of the drug himself.

Kohn spoke of the innocuousness of the drug. There were, to his mind, only two dangers to be guarded against, viz., the closure of the oesophagus or retention of urine from constriction of the urinary apparatus. Caries might also be a source of danger from the rapid inflammatory swelling that ensues, followed by the elimination of sequestræ. He disadvises its use in tuberculosis, although it increases the appetite, because at the same time it increases the fever and aggravates the general condition. In syphilis, on the other hand, it has no reaction, and may be administered with perfect safety, and may even be used as a differential diagnostic agent in obscure glandular swellings. In animal experiments excessive lymphorrhœa seems to follow the injections, which may explain in some degree the morbid action of the drug.

Spiegler remarked that thiosinamin was not the only body that acted on the periphery when thrown into the blood, and was only one of a number which determined reactive inflammation in morbid tissue. The amines generally had this property as well as many compounds belonging to the aromatic group, such as benzol, &c. Tuberculin has the same property as thiosinamin in decreasing a rise of temperature.

Mracek confirmed the foregoing testimony of thiosinamin, but added that it was a total failure in lupus and also in syphilis, either in the exanthematous or gummatous stage. On the other hand, in presence of

cicatrices the reaction is marked by a melting away of the scar, which becomes softer, more vascular, and compressible.

Weinlechner doubted if Teleky's case received the benefits from the drug which he attributed to it, as he applied the bougie at the same time, and he put the question whether nothing was due to the bougie?

We must await the decision of dermatologists on skin affections before dogmatizing on the specific efficacy of thiosinamin. They had many opportunities of testing its worth in keloids, &c.

Ullmann related four cases of keloids in which he had tried the drug, but without the slightest effect.

Teleky, in replying, said, in answer to Weinlechner, that he did not use the bougie after he commenced the injection of thiosinamin. He quite admitted that no reaction took place in lupus or syphilis or in specific ulcers.

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

TWO UNUSUAL CASES OF OVARIAN TUMOUR.—(1) Mr BATTLE operated on a woman, *et.* 65, at the request of Dr. Hector Mackenzie, under whose care she had been admitted. The patient was weakly, and suffered from chronic bronchitis; she complained of pain in the abdomen, especially below the umbilicus, and of some sickness. She had had pain in the abdomen for two or three weeks, and it seemed to her that this pain was getting worse, certainly it was no better; the abdomen was distended, tympanitic in the upper part, dull below the umbilicus, especially to the right of the middle line, and in this part a well-defined tumour could be mapped out, which fluctuated and gave a distinct thrill; there was a little fluid in the flanks, which shifted with position. The tumour was very tender on pressure, and the patient had a rise of temperature every evening. She refused operation for some days, although as a diagnosis of ovarian tumour, the pedicle of which had become twisted, had been made operation was urged. When she did submit to operation a cyst of brownish, somewhat mottled, appearance was exposed, to which omentum, small intestine and large intestines were all adherent. The omentum was rubbed back off the cyst by means of dry sterilised sponges, and nowhere required ligature to arrest the bleeding; in some parts small intestine could be separated in a similar manner, but in other parts it was necessary to divide adhesions of old standing between two ligatures. The contents of the cyst were somewhat chocolate-coloured, evidently containing altered blood, but were not offensive. The pedicle which was attached to the right side of the uterus was twisted from left to right for two and a-half turns, so that no blood could pass along it to the tumour, the nourishment of which must have been derived from the adherent omentum and intestine. A double ligature was applied to the pedicle close to the uterus, one of the ligatures being again tied so as to include the whole pedicle. The bleeding from the omentum, which was chiefly a general oozing, was arrested by the application of hot saline solution. The abdomen was cleansed and the wound closed without drainage. Mr. Battle considered the chief interest in the case arose from the fact that

changes were taking place in the cyst as the result of lowered vitality, owing to the twist on the pedicle. During the operation no vessel of any size was encountered, and the omentum appeared to supply most of the nourishment by means of its comparatively recent attachments; these adhesions had taken place comparatively recently, and probably since the final twist of the pedicle, for the omentum was adherent to the upper and anterior aspect of the cyst, and had evidently not been carried round with the rotation of the cyst when that took place. Three weeks after operation the patient, although rather weakened by her bronchitic cough was otherwise well, having lost all abdominal symptoms and was able to get up.

(2) The second case was that of a woman, *æt.* 54, who had noticed for some months a tumour in the lower abdomen, which was increasing in size but was not painful. On examination of the abdomen which was well covered with fat there was a tumour to be felt extending almost to the umbilicus, to which were attached one or two pedunculated and very movable tumours, which seemed more elastic than the general mass. Douglas's pouch was filled with this tumour, and the uterus, which was pushed forward, moved when the growth was moved. The patient was anxious to have something done on account of the discomfort of the tumour, and the fact that it was growing. At the operation when the tumour was exposed it was at first difficult to make out its nature and its relations to the uterus; the pedunculated growths were of some size and were evidently cystic, they were attached to a large tumour which occupied the pelvis and which contained a good deal of solid material; it could not be lifted out of the pelvis. After the incision had been further enlarged, it was found that the uterus was of normal size and pushed forwards over the pubes, whilst posteriorly it was involved in the wall of a cyst which filled up Douglas's pouch, and across which could be seen stretched the Fallopian tube. This cyst was embedded in Douglas's pouch, and its removal was a matter of considerable difficulty. The superficial cysts having been emptied of their fluid to give better access to the pelvis, the Fallopian tube and vascular bands by the side of it, near the uterus, probably composing the pedicle, were ligatured, and the cyst shelled out from its bed with considerable difficulty by means of the finger and occasional use of the scissors. During this separation one of the cysts ruptured, and a thick, creamy purulent fluid escaped on to the sponges which had been packed round. A smaller cyst about the size of the first could be felt on the left side of the uterus, less firmly attached than the right one, but held down immovably towards the lower part of the pelvis; this was found to be due to its attachment to another cyst which was of similar size and embedded in adhesions lower down; it was, however, much more easily shelled out than the cyst on the right side of the uterus, and formed, with the one above it, a curious hour-glass appearance. The pedicle on this side having been secured before the cyst was separated from other adhesions, nothing further remained to be done excepting to apply ligatures to the best organised adhesions which contained vessels, cleanse the pelvis, remove the sponges, and close the wound. Mr. Battle said that the case was

one in which the diagnosis was difficult to make between multiple fibroids and multilocular ovarian cyst. The patient being very stout, it was not easy to say that there was fluctuation in the pedunculated tumours which were attached to the main mass; they felt like subperitoneal fibroids attached to an enlarged uterus possibly containing fibroids in its substance. The whole mass was evidently attached to the uterus, if not part of it, whilst the position of that organ pushed upwards and forwards behind the pubes prevented a satisfactory examination being made. It was, he said, a very difficult operation, and at one time on first inspection it appeared almost beyond attainment. The main cyst had evidently developed from the right ovary, and the largest cystic portion had grown in the pelvis after a twist backwards. The left ovary had developed the hour-glass shaped tumour, and it was somewhat of a surprise to find the second cyst behind the first tucked into the pelvis, which the large cyst on the right side had appeared to fill so completely. It was, he thought, worthy of note that in spite of all these firm adhesions the patient had had very little in the way of pain.

WEDNESDAY, FEBRUARY 5, 1902.

THE ARMY MEDICAL SERVICE.

THE address delivered by Mr. C. B. Ball before the Dublin Branch of the British Medical Association is worthy of the closest attention. In the first place, the topic itself is engrossing, and one which calls for earnest consideration from all members of the medical profession who regard the future of that profession as a matter of importance. In the next place, Mr. Ball speaks *ex cathedra*. He is a member of the newly-constituted Advisory Board for Army Medical Services, and consequently, not only may his pronouncements be implicitly accepted, but the trend of his opinions, as shown by his words, may be taken as indicating to a certain degree the trend of the intentions of the Advisory Board. When the report of Mr. Brodrick's Committee was published, it was—as was only natural and right—submitted to severe criticism, with the result that certain points were detected in it on the inad-

visability of which the majority of authorities were agreed. Perhaps the chief of these—certainly the gravest but for its obvious impossibility—was the apparent recommendation that, if an officer of the rank of captain presented himself for the examination for promotion to major, and failed to pass, he could be compulsorily retired without any gratuity; while if he had not presented himself for examination, but had elected to retire as soon as he had completed his service as captain, he was awarded a gratuity of £1,000. Such a condition of service was, as we have said, an obvious impossibility; but nevertheless, when we think of the light-hearted manner in which the present, and indeed all Governments, attempt impossibilities, it is satisfactory to receive the definite assurance of a member of the Advisory Board that no such regulation had ever been contemplated. The remarks let fall by Mr. Tobin, in proposing a vote of thanks to Mr. Ball for his address, drew attention to a very salient point in past so-called army medical reforms. "Many commissions had recommended increased pay. In some cases the increased pay was given. In no case was there any difference in the Estimate for the Army Medical Department for the ensuing year. The Army Medical Department has been fed on its own tail. The increased pay had no effect on the Estimates because the number of officers had been correspondingly decreased." There is an important moral in Mr. Tobin's remarks. To effect a real reform in the Army Medical Service there must be an increasing annual Estimate; otherwise, what is given with one hand is taken away with the other. Of what use as a reform is increased pay, study leave, examinations for promotion, and the other recommendations of Mr. Brodrick's Committee, if at the same time the ranks are reduced? Increased pay in return for increased work is not a reform. The promise of study leave is of no avail when there is no chance of even holiday leave. Examinations for promotion are a weariness of the flesh when there is no time to prepare for them. Now, however, it seems that the medical profession may congratulate itself that these gloomy remarks are but the reminiscences of things which were. We think that we can read sufficiently between the lines of Mr. Ball's speech to see that the coming reforms will be *bonâ fide* reforms, and that an increased Estimate will follow as a result of increased pay and of an increased *personnel*. The much-expected warrant will, we learn, soon be issued, and with it we trust will come a new era for the Army Medical Service. The War Office takes a long time to learn its lesson, but it must have learnt it by this time. At present the Army Medical Service exists in great part through the patriotism and self-sacrifice of the medical profession. But, like the terms of the engagement of civil surgeons for the Cape, this patriotism and self-sacrifice will only last for "a year, or until the war is over." After that we trust that the interests of the country, or the short-sighted policy of the War Office, will no longer demand it.

QUACK AND CRIMINAL ADVERTISEMENTS.

IN many ways the public newspaper press is one of the greatest of the social forces at work in the advancement of the best and highest interests of mankind. Of late years the general tone of journalism in the United Kingdom has shown a great advance in morality, in culture and in the recognition of individual responsibility. There are, of course, black sheep among the flock, but even apart from those there is room for improvement in various directions, of which that which concerns the insertion of objectionable advertisements may fitly engage the attention of a medical journal. The respectable leading newspapers for the most part, although not absolutely, have purged their columns of the cures for venereal disease, of india-rubber preventives described in glowing terms, and of ladies' safe remedies, which are often simply veiled invitations to abortion, to be used afterwards as a means of levying blackmail. There are certain Sunday papers, however, that insert these announcements wholesale, while country and provincial newspapers distribute these filthy, prurient and often criminal advertisements broadcast. That the editors are aware of the real nature of the material they are inserting is shown by the fact that a special high rate is charged for insertion. That practice was proved in court at the trial of the notorious Madame Frain abortionist gang in London some years ago. From the legal standpoint it seems clear enough that any editor inserting advertisements of the abortionist type becomes accessory to a criminal act, and the matter comes at once within the jurisdiction of the police. In the absence of any satisfactory system of public prosecution it seems hopeless to look to the police for protection. The criminal law of the United Kingdom appears to be administered in such a way as to permit the authorities to shirk as much as possible the prosecution of frauds upon the public. When a fraudulent company director, a moneylender, a society rogue, a thieving charity-monger, or an artful swindler generally is brought to the dock, in nine cases out of ten his appearance is due to the efforts of a private citizen instead of the public official who adorns the Home Office. In all the topsy-turvydom of modern social institutions there is none more suggestive of farce than the office of the Public Prosecutor, and nowhere is he more ludicrously nonchalant than in the matter of fraudulent and indecent advertisements. Yet by a stroke of the pen the Home Office could effectually control a great proportion of the evil by instructing the police to prosecute, and so cutting off the advertisement without which quack practice of the kind would cease to be a profitable trade. There is another class of advertisements dealing with quack medicines the delusive nature of which must be evident on the face of them to any sensible man, quite apart from any medical knowledge. For instance, a "liquid fruit" cure that claims to cure the worst attack of whooping-cough in seven days must of necessity be fraudulent. Appended to that claim is the assertion that "all drugs

are poison." Yet an advertisement of that kind is published in so respectable a paper as the *Morning Leader*. Can the editor of that journal disclaim responsibility for the publication of statements that as a candid and cultured man he must know to be false? But that kind of advertisement is to be found more or less in every newspaper in the Kingdom. In one number of the *Illustrated London News* there appeared recently a whole page of illustrations advertising a notorious lung tonic, which claims to cure all kinds of lung complaints. It is needless to remark in the columns of a medical paper that no such medicine could by any possible manner of means be devised in the present stage of medical knowledge. In other words, the lung tonic is one of the host of frauds foisted upon the British public by the agency of newspaper advertisement. The *Daily News* has an announcement of pills "warranted to cure in either sex, all acquired or constitutional discharge, from the urinary organs." The pills are sold in boxes at four shillings and sixpence. For sheer brazen, petty and impudent quackery this advertisement would be hard to beat. It is an open advertisement of a gonorrhœa cure and it is hard to imagine how the editor of a newspaper of standing can permit his columns to be contaminated in such a fashion. The well-known weekly journal, *M. A. P.*, has several advertised cures for drunkenness, which experience has shown as a rule to belong to a cruel class of fraudulent quackery. The list of offenders might readily be lengthened, but enough has been said for the present. At some future time should the evil of which we have spoken still continue we shall conceive it to be our duty to deal more emphatically with offending journals. Several London newspapers receive large sums for advertising the Drouet system of cure for deafness, a fraud of a particularly cruel character which has been exposed by our trenchant contemporary, *Truth*. The whole subject is well worthy the attention of Parliament.

OÖPHORECTOMY FOR CANCER.

AMIDST the conflicting opinions as to the value of Beatson's operation we prefer to wait for further evidence. In the meantime we should neither rashly condemn an operation which offers the only hope of life to many victims of cancer, nor lightly hold out hopes to patients that are doomed to disappointment. Just as the medical profession had almost arrived at an adverse decision on the question, Dr. Robert Abbe comes forward with a record of seven successful operations. Five of these were performed so recently that he withholds their history for the present. He gives (*New York Medical Journal*) the history of the two first, and they are so interesting and of such great surgical importance that we give the principal facts of each. The first case was one of recurrent cancer in a woman forty-two years of age, whose breast and axillary glands had been removed ten months previously. At the time of the operation a nodule of cancer was found in the opposite breast. A week after Beatson's operation

changes in the cancerous growths were noticed, and at the end of eight weeks no trace of the disease could be found, and four months afterwards the patient remained well. The second case was more remarkable. The patient was seventy years old, and two years previously Dr. Beatson had removed from her a typical carcinoma. The growth recurred at the site of the incision of the previous operation, and as in the former case, the retrograde changes in the cancer were noticed at the end of the first week after the operation. At the time of the report, three months from the oöphorectomy the nodules were still present, and had recently showed less rapid progress, and were still slowly wasting. Although the patient was seventy years old, the ovaries were normal though atrophied. Dr. Abbe considered that the seven patients were one and all beyond hope of recovery when operated on. A little later Mr. Butlin, at St. Bartholomew's Hospital delivered a counter blast to the eulogy of Dr. Abbe. In a clinical lecture he warned his class not to be led astray by curious and abnormal cases, and declares that a permanent cure in no case may be looked for—permanence is wanting. He considers cancerous cases as belonging to three groups:—(1) Those in whom there is no complication and the disease does not recur for ten, fifteen, or twenty years. (2) Those in whom the axillary glands are implicated, in which the disease occurs *in situ* in a few years. (3) Those in whom the disease creeps up into other positions in the body with recurring *in situ*. Of Beatson's operation and treatment he believes that in not a single case is the result equal to that obtained by excision, and that when the disease recurs *in situ* it does so in exactly the same form and with all the same suffering as before, and the manner and distress of the patient's death are not in the least changed by the operation. This, however, we think goes too far; a long cicatrix extending to the humeral border of the axilla has occasionally involved some of the trunks of the axillary plexus, and been attended with the utmost agony. Of Beatson's operation it may by its advocates be fairly said that it is recommended for such cases as are inoperable, cases in which operation *in situ* has proven unsuccessful, and in whom a repetition of the ordinary excision holds out no hope. The patient is already weakened by the operation of excision, and the recurrence finds her without hope in its efficiency. Besides this oöphorectomy has no influence for evil on the disease, it may have some for good, and as practised to-day it is one of the safest of the major operations. Before dismissing the subject it would be well to recall the clinical experience on which Beatson based the value of the operation when in 1896 he brought the subject before the Edinburgh Medico-Chirurgical Society. He brought under notice three cases of scirrhus. One, a recurrent growth involving the chest wall, which, under the thyroid treatment, did not seem to do any good, the ovaries and tubes were

removed, and twelve months after the patient was well. The second case showed diminution of size of tumour, a disappearance of pain and a microscopic examination showed that the cancer was undergoing fatty degeneration. With Mr. Beatson's theory that pathological condition of the ovaries was the exciting cause of mammary carcinoma we are not concerned. But the experience of Beatson, Cheyne, Stanley Boyd, and Hobday shows that oöphorectomy influences cancer of the breast favourably, though we cannot as yet say permanently. That there is a relationship between oöphorectomy and atrophy may be taken as proven, although a few may still contend that it is casual, and on this hypothesis rests the justification of Mr. G. Beatson's operation.

Notes on Current Topics.

The Small-pox in London.

As, in our last issue, we ventured to anticipate, the slight decrease of the number of fresh cases of small-pox in London pointed merely to a lull in the storm. That view has been fully borne out by the figures of last week, which showed 78 new cases notified on Thursday, 82 on Friday, and 75 on Saturday, while the total number of cases under treatment at the Asylums Board hospital reached 1,136 at the end of the week. A medical man is being prosecuted by the Borough of Holborn for neglecting to notify a case. From his alleged negligence it is said that twelve other cases and one death resulted, but the summons for the present stands adjourned. The most important official step recently taken with regard to the stay of the epidemic has been the order of the London County Council rendering chicken-pox a notifiable disease for three months after February 6th. Numerous instances of mistaken diagnosis in that direction have been brought to light during the last six months, and common action on the part of the local authorities is a most desirable and necessary safeguard. Hitherto the action of the various boroughs has been erratic, for while some adopted the notification of chicken-pox six months ago, others, such as Westminster, have only recently followed suit; while others, again, have done nothing at all in the matter. As late as January 16th last, Dr. Sanders, Medical Officer of Health for West Ham, was mainly instrumental in procuring the rejection of that step by the Borough Council. It is not altogether easy to understand a position of that kind in view of the fact that the notification of chicken-pox now and then furnishes a sound means of checking the spread of the more serious disease, while on the other hand it is a harmless procedure. The "shelter" houses for the reception of families who have been exposed to infectious disease have done yeoman service in the present small-pox outbreak. The Borough of Stepney, in order to render them still more efficient, had decided to supply all inmates with food in order to obviate the need for outside purchases. There has been a sharp outbreak in the Mile End Infirmary, the limits of which it would be

impossible at present to forecast, as many crowded wards appear to have been exposed to infection. Curiously enough, Mile End, which is obviously an anti-vaccinationist district, has not hitherto been visited unduly by the small-pox. Unfortunately, however, there is serious reason to fear that the epidemic is destined to attain alarming dimensions within the space of the next few months.

Alleged Arsenical Beer Poisoning at Halifax.

WE have in a former number referred to the beer scare in Halifax which has arisen from the death of an aged hawker, due, as Dr. J. F. Hodgson declared at the inquest, to chronic arsenical poisoning. From the reports of the coroner's enquiry it seems Mr. A. H. Allen, Public Analyst for the West Riding of Yorkshire and the City of Sheffield, detected arsenic in quantities varying from $\frac{1}{10}$ th to $\frac{1}{4}$ th grain per gallon in various samples of beer obtained from Halifax public-houses. In three ounces of the liver from deceased $\frac{7}{10}$ th of a grain of arsenic was obtained. In spite of the medical and chemical evidence the jury found death to have arisen from "natural causes." After the recent painful experiences in the North of England it may be hoped that medical officers of health will keep a keen watch on the brewers and see that the analysts have full opportunities of investigating their products. It would be reassuring to know what steps the health authorities of Manchester and Salford, Liverpool, Blackburn, and other important centres are taking to ensure the protection of the public from arsenical poisoning. It is to be hoped, also, that the matter will have the attention of the Local Government Board. Meanwhile, the publication of the report of the Royal Commission on Arsenical Poisoning will be awaited with interest.

The After-care of Inebriates.

AT the last meeting of the Society for the Study of Inebriety the recognition of the necessity for a judicious "after-care" of inebriates was urged. At present the facilities for exercising an efficient management of inebriates are wofully inadequate in this country. Suitable institutions are limited. The so-called "homes" or "retreats" in only too many instances need to be converted into special inebriate hospitals where supervision may be effectual, treatment conducted on scientific lines, and a high level of discipline always maintained. The "private homes" are open to many objections. We strongly object to the conduct of any such places unless under strict medical inspection. But the discouraging returns of many of these institutions is dependent not altogether on defects in the management of these cases, but because the restored inebriate is in most instances sent back to the old alcoholic environment, and with feeble powers of resistance readily falls a victim to re-alcoholisation. The exercise of a tactful and scientifically directed "after-care" might accomplish much for the unhappy sufferers from the "drink craving."

The Post-Mortem on Czolgosz.

Few public events of recent years have raised so many points of intense interest for the medical profession as the assassination of the late President of the United States. Physicians and surgeons were equally interested in watching the course of events after the dastardly deed had been perpetrated. Alienists and medical jurists closely followed the details of the evidence as far as their particular branches were concerned in the trial which followed, and pathologists were unfortunately not uninterested onlookers; but interesting to all as are the details of the trial where they enable an estimate to be formed of the state of mind of the assassin, still more valuable, from a scientific standpoint, are the details of the post-mortem examination made on the body of the miserable Czolgosz. From a fairly complete account given by Dr. Spitzka, of New York, we have measurements of the head and body, with pictures of the cast of the head and sketches of the convolutions very carefully described. Needless to say the reporter keeps constantly in view the Polish parentage of the assassin, in so far as the notable features found corresponded with what was to be expected in a member of the Polish race. No doubt many opinions will be expressed on the report, especially on that portion which refers to the brain. We notice that beyond giving its weight no illustration or description is given in this official report of the condition of the cerebellum. The author observes that "So far as our knowledge of the correlation of brain-structure and brain-function extends, nothing has been found in the brain of this assassin that would condone his crime for the reason of mental disease due to intrinsic cerebral defect or distortion."

The Children's Sale of Liquor Act.

THE Children's Act, as it is commonly called, has now been several weeks in operation and so far the resulting prosecutions have proved more satisfactory than at one time we ventured to anticipate. The obvious rock ahead was the possible evasion of the Act by gumming a label across the cork of a bottle and claiming it as a "seal." The particular question has been raised at Peterborough, where a publican was summoned for selling to a child stout in a bottle which bore a gummed paper over the cork, such seal being recommended to the trade by the local Licensed Victuallers' Association. The police evidence was to the effect that although the bottle was securely corked yet the seal came off directly it was touched and without breaking. The Magistrate held that a slip of gummed paper did not constitute a seal and without convicting ordered defendant to pay the costs. In a similar case at Folkestone the Bench inflicted a fine of five shillings and fifteen shillings costs. In a London police-court last week an Inspector admitted that if the gum were dry on the label he would accept it as a "seal." The picture of the publican on the one side of the bar and the child on the other waiting for the label to dry is worthy the attention

of a comic journal. It is to be hoped in the interests of the younger population of the United Kingdom that the magistracy generally will take the common-sense view that decides against a gummed label as a seal. Otherwise the object of a salutary piece of legislation will be entirely defeated, an outcome that would be specially undesirable inasmuch as the Child Messenger Bill is the only Parliamentary achievement in the direction of much-needed temperance reforms.

Cheese and Cream Poisoning.

CHEESE poisoning is now a well-recognised occurrence, although it may be doubted whether the medical profession generally is quite alive to the facts of the case. A most interesting outbreak of the kind has been recently investigated by Dr. G. Newman, Medical Officer of Health to the Metropolitan Borough of Finsbury. A consignment of Dutch cheeses traced to a wholesale firm was beyond doubt the poisonous agency. The total number of cases attributed to that particular cheese was seventeen. The symptoms—namely, epigastric pain, rigors, vomiting, diarrhoea, prostration and some fever—came on from two to eight hours after eating the cheese, and there were no fatal results. Attention was first drawn to the fact of cheese poisoning by the severe outbreaks that took place in Michigan, U.S.A., in 1883 and 1884. No less than three hundred persons were affected, and the illness was traced by Professor N. C. Vaughan to a poisonous ptomaine present in the cheese. A similar poison is sometimes met with in cream and produces the same symptoms. It is probable that this ptomaine to which he gave the name of tyro-toxicon, is a product of bacterial fermentation. The report of the Public Analyst for Finsbury, Mr. Colwell, showed the presence of the tyro-toxicon in the incriminated cheese. He also showed that it was unequally distributed, not only among the different cheeses of the consignment but also in different parts of the same cheese. The same gentleman suggests that the provisions of Section 7 of the Sale of Food and Drugs Act, 1899, which requires every manufacturer of margarine or margarine cheese to keep a register showing the quality and destination of every consignment sent out, should be extended to cheese, with increased inspectorial powers to the medical officer of health. The suggestion appears to be both sensible and practical.

Suggested Royal Commission upon Cancer.

THESE are the days of government by Royal Commission, a device that is unrivalled by way of shelving the settlement of inconvenient questions. So far as the medical world is concerned three most important subjects have been recently dealt with in that way, namely, vaccination, tuberculosis and the London water supply. To appoint a Royal Commission does not bind a Government to accept the conclusions of the Commissioners, as shown in the case of Mr. Balfour's egregious Vaccination Acts. In the case of the Tuberculosis Commission the find-

ings were of a most practical and valuable kind, and will no doubt form a permanent basis for future legislation. But tubercle stands upon a footing very different from cancer, and it is difficult to conceive how the investigations of a hybrid scientific body could throw any fresh light on the causation and prevention of cancer. The best of all commissions of inquiry is that which is going on day by day among the surgeons of the United Kingdom. Until the specific cause of cancer can be demonstrated there is little prospect of ousting this scourge of mankind from its vantage ground. Meanwhile, the medical profession will cordially endorse Mr. Balfour's attitude in declining to consider the appointment of a Royal Inquiry upon cancer. Last week he stated in the Commons that he did not regard the cases of tuberculosis and cancer as at all parallel, and he thought it would be better to leave the subject of cancer in the hands of the medical profession in all countries. A handsome grant for special research made by Mr. Balfour's government would be more to the point than half-a-dozen Commissions.

Provision for Lunatics in Lancashire.

A CONFERENCE consisting of representatives from various boards of guardians in the county, was recently held in Manchester, the question of asylum accommodation for lunatics providing food for debate. The guardians have evidently had some difficulty and anxiety during the last year owing to the want of accommodation in the county asylums for dangerous lunatics. Cases have been referred back to the workhouses because of scarcity of accommodation, and perhaps this action of the superintendents was a very wise one, as overcrowding in an asylum is certainly a very serious matter. The tendency of workhouse guardians, nowadays, is to send off to an asylum without hesitation every patient who proves of wet or dirty habits, or who wanders about the dormitory at night, in fact, any chronic case who requires a little extra care or supervision. Such cases, whose chances of recovery are *nil*, are drafted into asylums and this has perhaps a good deal to do with the overcrowding in asylums everywhere, about which we have heard so much lately. If Poor-law guardians considered the question of establishing a system of night nursing in workhouses, fewer patients would require to be certified and sent to an asylum, and very soon the expediency and economy of this scheme would be clearly proven. Then, again, overcrowding in asylums would be to a large extent also obviated thereby. It was unanimously agreed that a deputation of twelve wait upon the Asylums' Board and confer with them on the subject. We shall watch the result of their mission.

ACCORDING to a statement made in Parliament a few days since the last examination for appointments in the Royal Army Medical Corps was held in February of last year, when twenty-two vacancies were offered for which only ten candidates competed.

Christian Science Possibilities.

THE basis of the so-called Christian Science treatment is the assumption that the influence of the mind on the body is such that sensations and even morbid conditions can be virtually abolished by intense mental processes. That mere sensation can be abolished by mental stress is a well-known fact, and very tangible physiological effects can be induced thereby, as, for instance, the whitening of the hairs as the result of powerful emotion, sudden aphasia, &c., and this in spite of the dictum that even philosophers do not bear toothache patiently. That the mind possesses any empire over organic lesions, however, is open to question, and is moreover unlikely except in so far as the latter may be influenced for better or for worse by a modification of the general nutrition. This influence is asserted to exist by the advocates of faith-healing, but its concession would involve the admission of the converse proposition—viz., that if the mind can remedy diseased conditions it must likewise be capable of inducing them. This amounts to a resuscitation of the witches' bane, the ability to induce diseases having for centuries, and possibly longer, been universally regarded as inherent to witchcraft, whence the fear and loathing with which reputed witches were regarded. We would rather relinquish the former hypothesis than be constrained to admit the latter, for orthodox practitioners would be nowhere if their faith-healing rivals could attract sheep to their folds under menace of worse to come.

Antigua as a Prisoners' Health Resort.

THE selection of Antigua, one of the healthiest and most beautiful of the Leeward Islands, as a site for Boer prisoners tells of the clemency and consideration that is being shown to the brave men who have so long and sturdily resisted our forces. Columbus discovered the island on his second voyage, and was surprised to find it had no inhabitants, which may be accounted for by the fact that there is no river on the island. The absence of the fierce Caribs and the beauty of its flora made it in the eyes of the great navigator an earthly paradise, and he named it *Isla Santa Maria de la Antigua*, in honour of the famous church in Seville, which was then being completed after almost a hundred years' labour, having been commenced in 1401, on the site of a Moslem mosque. The island is twenty-eight long and about fourteen broad; it was colonised in 1623 by some English families, and in 1666 Lord Willoughby, having had a grant of the island from Charles II., made a settlement with some emigrants on the shore near to where the town of St. John is now situated. The principal elevation in the island is Boggies' Hill, which attains an altitude of more than 1,300 feet. There are numerous brackish springs on the island, and it is hoped that the deficiency of good water will be remedied by sinking artesian wells. Antigua produces large quantities of sugar, pineapples, tamarinds, arrowroot, and cotton. Since the sanitary laws have been enforced yellow fever is unknown in the country,

and the absence of fresh-water pools may account for the immunity the island enjoys from malaria, and the last recorded epidemic of dengue that visited its coasts is said to have been January, 1828. Although completely surrounded by the Gulf Stream, the temperature of Antigua seldom exceeds 90° F., and does not fall below 70° F. In such a delightful climate the Boers will have little to complain of in their enforced expatriation, which we hope a lasting and honourable peace will soon end.

Identification of Finger-marks.

WE have received from Señor Juan Vucetich a copy of his address on the value of finger-prints as a means of identification. He follows the same line of argument as that adopted by the author of "Puddin Headed Wilson." In the one case a brilliant novelist detects, after many years, a crime, in the other the finger-marks are used as the ordinary method of identification. The pamphlet is interesting as giving the history of the application of the method for the detection of criminals. In 1858 Sir W. J. Herschell, when Governor of Bengal, had impressions taken of the thumb and index finger of the right hand of all criminals within his jurisdiction. And the ingenious Gilbert Thompson, Governor of the State of New Mexico, had the impression of his right thumb marked on all his official papers, as a protection against forgery. The impression of the finger remains unchanged, and the lines on the front of the finger are unaffected by age, work, or cessation of work, so that years afterwards, when the hair, face, figure, even the stature and colour of the eyes have been affected by age, the finger-marks remain unchanged. There is but one risk, to wit, the blurring of the impressions in the police office; to reduce this to a minimum, an impression is taken of each of the ten fingers in Buenos Ayres. The value of such evidence in medico-legal cases he illustrates by some cases that came before the authorities in La Plata. In one case, in 1892, the finger-marks of a murderess led to her conviction. To obtain clear, well-marked impressions of the pulp of each finger from the joint to the free extremity it is necessary to exercise a good deal of care, and requires some practice; the method adopted in Buenos Ayres is shown in the pamphlet by numerous good illustrations.

Antidotes for Morphine.

OF all the reputed physiological antidotes of morphine none would seem to compare with cocaine. This alkaloid exerts a very marked antidotal action even at an advanced stage of opium or morphine poisoning. The only drawback to its use is that the doses required to combat the toxic effects of opium or its alkaloid are so large that the patient on recovering therefrom may have to go through a stage of cocaine poisoning, which is associated with very distressing sensations. It is recommended to give half-grain doses of cocaine, at intervals of half an hour, until consciousness returns and breathing is normal.

Medicinal Scar Solvents.

CERTAIN drugs, the outcome of recent research, appear to exert a very marked action in promoting the yielding and preventing spreading of cicatricial tissue, a property which promises to be of the greatest value in the treatment of cicatricial strictures not readily accessible to surgical measures, especially as their action is not topical but constitutional. Our Austrian correspondent gives some interesting details concerning the results obtained in eight cases of stricture of the œsophagus caused by swallowing caustic potash, and although there is the usual conflict of opinion a good case would seem to have been made out in favour of the dissolvent action of thiosinamin. This is administered subcutaneously, and appears to be devoid of danger if employed with ordinary prudence. We are assured that thiosinamin is not unique in this respect, but its action certainly opens up a new vista in the treatment of strictures and cicatricial states in general. Our readers will doubtless await with interest the further development of this line of investigation.

The Disintegration of Victoria University.

EDUCATIONAL matters in England are in a somewhat chaotic condition, and unfortunately in matters medical, perplexity and uncertainty particularly prevail. Instead of the maintenance of a high standard of efficiency and a determination to a one-portal system of admission to the profession there is a tendency to lessen the stringency of examinations and to multiply the channels of entrance. The Victoria University, the great federal University of the North, which has rightly won a leading place in our national educational life, seems now about to suffer dissolution. Liverpool insists on having a University of its own, and general opinion seems to indicate that Leeds and Manchester must of necessity claim similar action for their respective centres. This premature disintegration is much deplored by many in the best position to judge of its probable detrimental effects on educational progress. It will be well for graduates of the Victoria University to see that in the impending changes their rights and privileges receive consideration and due protection.

Anti-Vaccinators Disconcerted.

CERTAIN prominent anti-vaccinators have endeavoured to make capital out of the difficulties which, it is alleged, have been placed in the way of their obtaining particulars concerning patients in the hospitals of the Metropolitan Asylums Board—particulars which they claimed the right to obtain in virtue of Section 8 of the Vaccination Act (1898). The matter was referred to in Parliament last week, when Mr. Long pointed out that the section of the Act in question applies only to sanitary authorities into which category the Board does not fall. The managers of the Asylums Board do not, however, appear to have availed themselves of this technical objection, but insisted on the regulation which provides, reasonably enough, that no one shall be per-

mitted to enter the ships until he shall have satisfied the medical officer that he, or she, has been efficiently protected against contracting small-pox. It may be assumed that none of the applicants was in a position to conform to this regulation, or else was unwilling to admit the fact. They may consequently have to wait for their information until such time as the particulars are embodied in the final report.

Methylic Amaurosis.

IN view of the alleged prevalence of the habit of drinking methylated spirit it is interesting to note one curious effect of the ingestion of methylic alcohol in large or repeated doses. In a number of cases more or less diminution of visual acuity has been observed as a sequel of methylic inebriety. This form of amblyopia is due to bilateral interstitial inflammation of the orbital portions of the optic nerves, and in the early stages the failure of vision is often characterised by the patient being able to see better in a subdued light. There is no diminution of the fields of vision; indeed, peripheral vision may be better than central vision. Another characteristic feature is the inability to distinguish red and green in the centre of the visual field constituting what is called a central scotoma for these colours. The prognosis in these cases is good, provided, of course, that the cause of the trouble be removed. It is worth noting that this form of retrobulbar neuritis has never been known to follow the ingestion of ethylic alcohol, and this constitutes another reason, apart from the difference in taste, for preferring even inferior whisky to the methylated substitute.

An Early Vaccinator.

IN our versatile contemporary, the *Tatler*, an excellent illustration is given of Mr. Benjamin Jesty, a jolly Dorsetshire farmer, who, so it is contended, as early as 1774, when the village of Yetminster, where Jesty's farm was located, was being ravaged by small-pox, vaccinated his wife, his children, and himself with cow-pox. Doubtless it will interest our medical historians to ascertain on what grounds this claim of Dorsetshire to take precedence over Gloucestershire in matters variolous really rests.

Rate-paid Revaccinations.

THE folly of inducing, or even allowing, well-to-do persons to be revaccinated at the expense of the ratepayers is beginning to be appreciated in the Press, and when ratepayers as a class discover how many hundreds of thousands of pounds have been wasted in this way there will assuredly be an outcry against a practice which is as contrary to public policy as it is to the legitimate interests of the private practitioner. An unauthorised statistician has calculated that the sum thus expended in England alone during last year exceeds £1,500,000 sterling, but this sum, no doubt, includes many revaccinations, the expense of which might properly fall on the public funds. The unblushing touting for

patients to which public vaccinators have of late resorted under cover of Local Government Board instructions has aroused great indignation in medical circles, and may be expected to be the subject of further discussion.

Puffing Journalism.

THE *Daily Mail*, with flagrant disregard of professional usages, and in defiance, it may be assumed, of the wishes of the persons immediately concerned, has inaugurated a series of articles eulogising individual methods of treating consumption and their discoverers. They are characterised by the lack of discrimination and sense of proportion which are usually manifested by the newspaper reporter when let loose on an errand of this description. While we welcome the disclaimers of the medical practitioners whose investigations have been converted into vulgar "copy," we would point out that knowingly to receive a representative of the Press is to expose oneself to experiences of this kind, for no importance can possibly be attached to the promises of one whose view of his calling is inconsistent with delicacy or reticence.

Ad Valorem Fees.

A CURIOUS action was recently tried in the Rothesay (N.B.) County Court, in which a medical practitioner sought to recover fees on a higher scale than that comprised in an account previously rendered. In the original bill the visits were charged for at something between nine and eighteenpence each, but as the patient turned out, on her affairs being made public, to be a woman of means the claimant maintained that he was justified in rating his services at a higher figure. The Sheriff admitted that the claim puzzled him, but unfortunately the report before us does not give his decision. Perhaps he is still considering it.

The Superabundant Female.

IF numbers mean anything the female is the dominant element in London life. The recently-published returns of the Census show that in the County of London the females exceed the males by over a quarter of a million. This disproportion is on the increase. Ten years ago there were 1,116 females to every 1,000 males, but now there are 1,118. This fact goes some way in throwing light on certain medical and sociological aspects of modern life. The increasing participation of females in business and public life is quickly bringing about a state of affairs which the hygienist cannot afford to neglect, and is doing much to make old standards useless and necessitating the introduction of new methods.

London's Centenarians.

THE revelations of the latest Blue-book dealing with the Census returns is particularly interesting to medical men and all interested in the sanitary state of the Empire's chief city. A feature worthy of special note is that which refers to those who are of advanced age. The Metropolis can boast of

twenty-four centenarians. There are nineteen females and five males who claim to be 100 years and upwards. The number of persons seventy-five years old and upwards is 52,679, and of these 18,776 are males and 33,903 females. This seems to show that should one desire a good chance of reaching senility it is well to live in London and be a female.

PERSONAL.

DR. JOHN SHIELDS FAIRBAIRN has been appointed Assistant Obstetric Physician to St. Thomas's Hospital.

MR. ALFRED WINKFIELD, F.R.C.S., has resigned the appointment of Medical Officer of Health to the City of Oxford.

THE latest reports concerning Professor Virchow are to the effect that "his present condition is far from favourable."

DR. DAVID J. ROBERTS, M.B.Ed., has been appointed Medical Superintendent at the Meathop Sanatorium, Westmoreland, in place of Dr. W. M. M. Jackson.

SIR JOSEPH DIMSDALE, Lord Mayor of London, announces his intention of presiding at the Festival Dinner to be given in aid of the funds of St. Mark's Hospital for Fistula and other Diseases of the Rectum.

DR. F. W. PAVY, F.R.S., is to take the chair at the Annual Dinner of the Fellows of the Royal Medical and Chirurgical Society of London, which is to take place at the Hôtel Métropole, on Wednesday, February 26th.

THE nomination of Dr. Kerr to the post of Medical Officer to the London School Board has been ratified by the Board. The post comports a salary of £800 per annum, rising by increments of £25 per annum to a maximum of £1,000. Dr. Kerr undertakes to give his whole time to the Board, and not to hold or accept any other office, appointment, or engagement.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

NOTIFICATION OF PHTHISIS IN EDINBURGH.

A PROPOSAL to make consumption a notifiable disease so far as Edinburgh is concerned, and also the question of hospital accommodation for advanced cases of phthisis, was under consideration in the Public Health Committee last week, when it was agreed to ask the Town Council to hold a special meeting to go into the whole matter. It is said that if the former proposal be carried there is every likelihood that an effort will be made to have the present Fever Hospital (the old Infirmary), shortly to be vacated for the new hospital at Colinton Mains, set apart for far advanced cases. An objection raised to this particular scheme is the market value of the old site—one of the most central in the town—and in the event of its being disposed of to the University authorities, who are understood to be offerers, another position for the proposed hospital would have to be found. The late Bailie Pollard, Convener of the Public Health Committee for many years, in his report for 1900, made the same suggestion. He estimated that an annual expenditure of £5,000 would support 100 beds, and from the experience of a similar municipal hospital in Paris that the average life of patients received into its wards is three months, that this would mean the annual removal of 400 feet of infection. Notification of

phthisis has been on the tapis in Edinburgh for the past year or two, and there seems little doubt that before very long it will be an accomplished fact. If we mistake not, Edinburgh was one of the first, if not the first, towns in these islands to adopt compulsory notification of infectious disease, and it is to be hoped that it will be similarly to the front in tackling consumption. Up till the end of 1901 it had a Notification Act of its own which differed from the general Act in that it included cases of measles, and excluded erysipelas and puerperal fever. With the beginning of this year, however, the special Act lapses, and the town comes into line with the rest of the country in adopting the general Act. Experience has shown that the notification of measles has been practically useless in checking the disease or diminishing its mortality, and it seems very questionable whether it is worth while including it as a notifiable disease. The only medical man on the Town Council, however, holds a different view, and an effort is to be made to have measles retained, even though the new Act is adopted.

SMALL-POX.

The number of patients now (February 1st) under treatment is forty-eight. The second death which has resulted from this outbreak of the disease is reported to-day.

MORISON LECTURES.

These lectures were this year delivered by Dr. George A. Gilson, in the Royal College of Physicians, Edinburgh. The subject dealt with was nervous disturbances of the circulation, only affections in which there were changes in sensation being discussed in the present series of lectures. In the first lecture the symptomatology was under consideration, the lecturer giving an historical résumé of the subject, which, described in a fragmentary way by the earlier writers on medicine, owed its first formal presentment to Heberden, who in 1768 gave an excellent description of angina pectoris. Jenner, and then John Hunter, has associated heart pain with lesion of the nutrient arteries of the heart, and, as a conclusion to the historical part of the lecture, the clinical observations of Balfour, Latham, Gardner, Head, and others were mentioned. The general features of heart pain were alluded to, and the last portion of the lecture was devoted to the classification of angina, the current division into true and false, or pseudo-angina, being, according to Dr. Gilson, unscientific and misleading, whereas the cases fall naturally into two groups—organic and inorganic; the former embracing those in which there is an obvious change in the heart or vessels, while under the latter head fall toxic cases, such as those due to tobacco, alcohol, microbial poisons, and the like, and neurotic cases, whether due to reflex spasm of the arteries, nervous debility, or hysteria. The second lecture was given over to an explanation of sensory cardiac symptoms on physiological grounds, an account being given of the growth of knowledge concerning the innervation of the heart from the time when Weber discovered the inhibitory action of the vagus down to the most recent work of Langley, Ramon-y-Cajal, Dogiel, and Morison. The main points insisted upon were that the cardiac ganglia were parts of the outlying sympathetic system, and that both in this system and in the vagus afferent and efferent fibres existed. The impulses conveyed to the heart by the vagus diminished cardiac activity; while those of the sympathetic (the "katabolic nerve," as Balfour has so well called it) increased the heart's action. While the exact paths of sensory impulses were less susceptible of investigation than those of motor impulses, there was ample evidence that impulses travelled from the heart to the cord by the sympathetic nerves. These afferent impulses were caused by the lesions and toxic or nervous influences mentioned in the previous lecture, and these, too, might render the normally insensitive heart sensitive. The brain, however receiving as it did the vast majority of its sensory stimuli from the cutaneous surface, was apt to mis-interpret the source of cardiac stimuli, and to mis-refer them to corresponding cutaneous areas, which had been demonstrated by Head and others. The concluding lecture

was devoted to the therapeutics of angina and cardiac pain generally.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

SUPERFETATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I beg to thank Dr. O'Gorman for the particulars of his case of supposed superfetation. I fear, however, I still am sceptical. Dr. Tyler Smith's manual may have recognised the possibility of superfetation, but the case which Dr. O'Gorman quotes from it does not prove the possibility of such an occurrence. I have read Dr. Bonnar's article in the *Edin. Med. Journ.* with much interest, but he, too, does not bring forward any proofs of such a possibility. To prove that superfetation is possible and has occurred, it is necessary to demonstrate the fact that two ova of different ages are contained in a single uterus at the same time. Before bi-manual examination of the pelvic contents was a recognised mode of examination the existence of a double uterus or of a uterus septus was overlooked. Consequently, from the want of knowledge of the condition of affairs present, superfetation was deemed possible, because it appeared to be the only explanation of certain cases. Once, however, it was shown that there was another explanation of these formerly puzzling cases, the impossibility of superfetation was allowed to make itself evident, and an impossible structure, which originated in necessity, crumbled to the ground.

There is no use in flogging a dead dog, and superfetation is as dead a dog "as ever lived." If Dr. O'Gorman has no doubt but that there was a difference in the age of the infants in the case he records will he make a careful bi-manual and intrauterine examination of his patient and communicate the results to your journal?

I am, Sir, yours truly, X.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In your issue of 29th ult. Dr. O'Gorman, under the above heading, relates two cases of supposed superfetation, one mentioned by Tyler Smith in his "Manual of Obstetrics," and the other occurring in his own practice. Both the cases, I venture to suggest, should be classed as "delayed developments" upon the following grounds. In both the secondary impregnation or superfetation is supposed to have occurred at least four months after the primary fertilisation of ova, an event almost impossible according to one's knowledge of what changes take place in the tubes and uterus after pregnancy commences, the difference in sizes of the foetuses and the number of the placentae being accidental and dependent upon the degree of vascularity of the area upon which the individual ovum alights. Thus in Dr. O'Gorman's case the two male ova fell upon soil rich in blood, and by their vigorous growth further depleted the area upon which the less fortunate female ovum took up her abode, with the ultimate result that two full-term males were born, and one female having the appearance of being only half-time.

Upon such an interesting subject as this, one might think and write much, but as its usefulness is doubtful I consider it better to let myself rest in the belief that superfetation after a few hours does not take place.

I am, Sir, yours truly,
ROBT. HUGH HODGSON, M.D.

SURGEON TO COUNTY INFIRMARY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I was much surprised to find that notwithstanding the County Infirmaries and Registration of University Diplomas Act, 39 and 40 Vict., cap. 40, an Order is made directing that none but those holding letters testimonial of the R.C.S.I. should be appointed surgeons to county infirmaries in Ireland, as you can see by reading Clause 86 of the Statutory Rules and Orders,

1899, No. 44, issued by the Lord Lieutenant and Privy Council of Ireland.

I have given you the title of the Order so that you may refer to the clause, as I am unable to send you a copy. This—if I am correct—would require to be seen to, as if an election for a surgeon was pending it might seriously injure, in fact, probably prevent one holding a degree from obtaining the appointment.

I am, Sir, yours truly,
ROBERT GRAY, F.R.C.P.

[Our correspondent quotes the Statutory Order correctly. It is a regulation which has not been adhered to in the past, but which could be enforced at any moment. The attention of the authorities of Dublin University and the Royal University should be drawn to its existence with the view to having the clause in the Infirmaries Act on which it is based removed from the Statute-book.—ED.]

THE MODERN TREATMENT OF CONSUMPTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—There seems to be an almost universal belief that the main features in the present system of treating phthisis are entirely of recent origin—dating, in fact, from a period subsequent to Koch's discovery of the tubercle bacillus in 1882. As the matter is one of considerable historic interest I shall be glad if you will allow me to point out that this opinion is altogether fallacious. At least forty years ago a distinguished band of Dublin medical men, prominent among whom were Graves, Stokes, and Marsh, taught and put into practice doctrines as to the treatment of the disease which are hardly distinguishable from those held to-day. It is true that they were not aware of the bacterial origin of the malady, and were ignorant of its contagious character, but nevertheless, in their repudiation of the theory of heredity, and their advocacy of fresh air and a generous diet, they were the real originators of the modes of treatment which are almost universally in favour to-day. I have been reading with interest Dr. Dennis Vinrace's useful book on "The Tuberculosis Congress," and, in perusing the comparison he draws between the therapeutic methods of former days as regards phthisis and those now prevalent, I have been much struck by the fact that practically all the points mentioned by Dr. Vinrace as constituting the dominating features of the existing system of treatment were adopted by these Dublin pioneers early in the second half of last century. Graves, for instance, wrote as follows:—"If a tiger from the wilds of Africa, who can boast of a line of ancestors as free from phthisis as any of us, be brought into this country, and debilitated by confinement, impure air, and a climate to which he is unaccustomed, you will frequently find that he will die phthisical." He went on to instance similar cases among monkeys, and specially refers to a dromedary, carried about for exhibition, which was dissected by the College of Surgeons, and found to have fallen a victim to consumption. The moral he drew was that the animals had contracted the disease through the effects of want of proper exercise and fresh air, and that it is to these conditions, among men as well as animals, and not to heredity, that the propagation of the disease is due.

In another passage he declared that phthisis could be proved by statistics "to depend on confinement, poverty, and vice," and he pointed out the ill effects produced by allowing young children to work for long hours in crowded, badly ventilated factories. Still more to the point are his criticisms of the modes of treatment favoured in his day, comprising "coddling, confinement to hot rooms, venesection, and low diet." These he denounced as being "circumstances which in due time would make many persons phthisical." His own views as to the proper treatment to be adopted he summarised as follows:—"A rational physician will endeavour to prevent its occurrence, not by confining his patient and wrapping him in flannels, but by hardening him against cold. Anyone who wraps himself up, and confines him-

self within doors takes cold in ten-fold proportion to the person who dispenses with superfluous coverings, washes his chest with cold water, and rises early. As to food, make your patient lay aside 'slops.' Let him take wholesome fresh meat, bread, and good beer. Let him also dine early and rise early, and let him remain in the open air four or five hours, taking exercise on a jaunting car or on the top of a coach." Could any speaker at the recent Congress have laid down a therapeutic and prophylactic system more in accord with what we consider to be the latest modern ideas? Clearly, however great are the advances we have made in knowledge of the prime cause of the disease, and of the best means of preventing its dissemination, we have really made little, if any progress during the past forty years as far as the discovery of new principles of treatment is concerned. The system adopted by the open-air sanatoria of to-day is in essentials the same as that practised by Graves, Stokes, and Marsh, of Dublin, and MacCormac, of Belfast (father of the distinguished surgeon whose loss we have so lately had to deplore), some forty years ago.

My object in writing this is not, of course, to depreciate the services of the many able men who have in our own day popularised and perfected the views first given to the world by this group of enlightened Irishmen. I wish simply to draw attention to the claims of my countrymen to a due share of the praise.

I am, Sir, yours truly,

JAMES HAMILTON, M.D., Q.U.I.

60, Sydney Street, Chelsea, S.W.,

January 25th, 1902.

A Medical Man Censured.

DR. VERITY, of Glendiffaith (Carnarvon) was censured by the coroner's jury for having delivered a certificate of death in respect of an elderly woman who had fallen into the fire, presumably in consequence of an attack of apoplexy. Inasmuch as Dr. Verity admitted that the burns must have accelerated death he was unquestionably in the wrong in giving the certificate, and it can hardly be supposed that he was unacquainted with the law on the subject.

Deaths under Chloroform.

A MAN, age 51, an omnibus conductor, died at St. Bartholomew's Hospital last week during the administration of chloroform preparatory to the opening of an abscess. Ether was used at first, but as he did not take it well chloroform was substituted. As usual, no details of the method of administration were forthcoming, and at the inquest the stereotyped verdict was returned. Another mishap of the same kind is reported to have occurred at the Great Northern Hospital, the victim being a man, age 29, who was suffering from pneumonia with pleurisy and effusion. He died before insensibility had been induced, a result which might almost have been expected, and one is tempted to ask why local anaesthesia was not resorted to in view of the risk inseparable from the administration of a general anaesthetic in a case of this kind.

Public Authorities and the Payment of Fees.

AN action was tried a few days since in which Dr. F. Bastow Cooper sought to recover fees due to him by the Bracebridge Urban District Council under the Notification of Diseases Act. The points at issue were, whether the plaintiff could legitimately be called upon to send a receipt for the amount before he had received the same, and also whether he was not entitled to be paid the amount due to him at his residence without the trouble of fetching it from the Council's offices. The matter was settled by the amount being paid into court, and this is perhaps a pity, because it would have been convenient to have a judicial decision upon these two points. We have no hesitation in endorsing the plaintiff's contentions, and it is to be hoped that the practice of asking for a receipt before payment of the amount due, a practice very generally adopted by sanitary authorities, will fall into disuse.

Army Medical Prize Distribution.

SURGEON-GENERAL W. TAYLOR, Director-General Army Medical Corps, last week presented the prizes to surgeons

on probation who were successful at both the London and Netley examinations, at the Army Medical School, Netley Hospital. Colonel M'Leod reported that twenty-six surgeons had proved themselves fitted to receive his Majesty's Commission. The Parkes Memorial Medal and M'Lean prize for clinical and ward work were presented to A. E. J. Lister; the Herbert prize, the prize in pathology, and the De Chaumont prize in hygienic to T. S. B. Williams; the Marshall Webb prize to S. H. L. Abbott; the Martin Memorial medal to E. Bisset; the first Montefiore prize and medal to E. A. Loch, and second Montefiore prize and medal in pathology to A. W. Overbeck-Wright, all of the Indian Medical Service.

A Scarcity of Cheap Doctors.

THE managers of the Tiverton Infirmary have had a trying experience in their endeavours to find a resident medical officer. In 1900 and 1901 they advertised for several weeks at a time for a house surgeon at £80 per annum, all found. To the first advertisement they received no application, to the second one from a lady, to the third three, all from ladies, and to the fourth seven, four from gentlemen and three from ladies. The committee appointed each gentleman in turn, and each gentleman in turn either declined to take up the appointment or agreed to do so and failed to carry out his agreement, except the last, who arrived, and was discharged the following day for gross misconduct. The committee, having then been without any house surgeon for some months, appointed the best qualified of the lady applicants, Miss E. McElney, who had since fulfilled the duties of the post to the entire satisfaction of the committee, including the hon. medical staff and the patients generally. The committee were informed that £200 per annum and all found failed to obtain gentlemen as house surgeons, and half that sum was more than the finances of the institution would warrant.

Post Vaccinal Death.

AN inquest was held at Horsey on the 31st ult. on the body of a man, age 60, a toll clerk in Smithfield Market, who had been vaccinated on January 15th. On the 24th he fell ill, and shortly after became comatose, dying on the 26th. At the autopsy meningitis with effusion was found, and this was attributed to septic mischief. The vaccination had run a normal course, and none of the other 106 persons vaccinated with the same lymph had had any trouble. The jury returned a verdict that death was due to septic meningitis following vaccination, adding that they would not state the origin of the septic condition, but that the vaccination was properly performed.

The late Surgeon-Major Metcalfe Johnson, J.P.

LANCASTER has lost a link with the past by the death of Dr. Metcalfe Johnson, at the ripe age of 78 years. Dr. Johnson was born at Wisbech in 1823, served his apprenticeship with Dr. Muriel, at Ely, became a student at Guy's Hospital in 1843, qualified in 1846, and at once settled in Lancaster, where for over half a century he has exerted a wide influence. He held various important public appointments, took much interest in scientific and literary studies, and was imbued with somewhat of the military spirit. With the soldiers he was very popular and familiarly known as "Old Iodine" on account of his fondness for painting them with this drug. Dr. Johnson's published writings include "The Monad's place in Nature," "Borderland," and "Hedonism." In 1872 he issued an "Invalid Cookery." He also took much interest in the study of the relation of crime to insanity and pauperism.

Dublin Death-rate.

THE annual death-rate in the Dublin registration area for the week ending Saturday, January 25th, 1902, represents an annual mortality of 21.7 in every 1,000 of the population. Tuberculous disease caused twenty-nine deaths. Diseases of the respiratory organs caused thirty-five deaths. Thirty-six of the persons registered were infants, of whom twenty-two were under twelve months' old. In six cases the deaths were "uncertified," there having been no medical attendant during the last illness.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

MATRON.—We are decidedly of the opinion that the hours of duty are too long, in view of the arduousness of the work.

EX-COLONIAL.—Apply to the Dean of the West London Post-Graduate College, Hammersmith, W., for a prospectus of the College.

DR. A. T.—Assuming the facts to be correct a suit for malpractice would be certain to fail.

A VERSATILE PHYSICIAN.

THE following (says the *N.Y. Medical Record*) is an advertisement published in Shakespeare's time:—"Wanted—for a family of invalids, a reliable and faithful man who is a competent physician, surgeon, and obstetrician; he must also take charge of the wine cellar and table service, and understand the cording of hemp, and construction of wigs. Every Sunday he will be expected to deliver a sermon, and, if necessary, conduct religious services. A liberal salary will be paid."

DR. E. A. (Budapest).—We have no means of ascertaining the detail you refer to in your first question. In reply to your second question, a practitioner who holds a resident hospital appointment requires to be qualified the same as if he were engaged in private practice. The practice of medicine is free in England, but a foreign graduate has no legal status, cannot sue for fees, sign certificates of death, &c. With regard to a treatise on surgery, we can recommend that by Rose and Carless (Baillière, Tindall and Cox), price 21s. net, or Walsham's "Surgery" (Churchill), price 15s. net.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, FEB. 5th.

OBSTETRICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Drs. Amand Routh, William Duncan, Mr. Bland-Sutton, and others. Annual meeting. The President (Dr. Morrocks) will deliver the annual address.

THURSDAY, FEB. 6th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Dr. W. Ewart: Scleroderma with Raynaud's Disease. Dr. Sidney P. Phillips: Epistaxis in Rheumatism.

NEUROLOGICAL SOCIETY OF LONDON (11, Chandos Street, Cavendish Square, W.).—8.30 p.m. Annual meeting. Mr. H. W. Page: Presidential Address on Concussion of the Brain in some of its Surgical Aspects.

ROENTGEN SOCIETY (20, Hanover Square, W.).—8.30 p.m. Mr. E. W. M. Shenton: On a System of Radiography.

FRIDAY, FEB. 7th.

LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover Square).—5 p.m. Cases and Specimens will be shown by Dr. Lambert Lack, Mr. Richard Lake, Dr. F. W. Bennett, Mr. Atwood Thorne, Dr. L. H. Pegler, Mr. Waggett, Dr. H. J. Davis, and Dr. Donelan.

SOCIETY OF ANESTHETISTS (20, Hanover Square, W.).—8.30 p.m. Clinical evening.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.).—8.45 p.m. Dr. E. E. Scholefield: Some Cases of Feigned or Functional Disease.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, Hammersmith Road, W.).—8.30 p.m. Discussion on the Treatment of Inoperable Cancer. Mr. Alfred Cooper, Mr. Stanley Boyd, Mr. H. T. Butlin, and Mr. Henry Morris will take part in the discussion.

THURSDAY, FEB. 13th.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. F. W. Ramsay, Mr. R. O'Callaghan, and Dr. H. Macnaughton-Jones. The incoming President, Dr. Halliday Croom, will deliver his Inaugural Address.

DUBLIN.

THURSDAY, FEB. 6th.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION (Front Hall, Trinity College).—8.30 p.m.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.

FRIDAY, FEB. 7th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Obstetrics.—Specimens.—The President: Uterus removed for Fibromyoma. Dr. Horne: Large Fibromyoma removed by Myomectomy. Dr. Alfred Smith: 1. An Ovarian Cystoma Strangulated by twisting of the pedicle. 2. A Solid Ovarian Tumour with Pyosalpinx. Dr. Purefoy: 1. Concurrent Uterine and Tubal Pregnancy. 2. Large Ovarian Multilocular Cyst removed soon after parturition. 3. Two Dermoid Ovarian Tumours removed from patient suffering from tuberculous peritonitis. 4. Small Ovarian Cyst. Papers.—Dr. Alfred Smith: Notes on a Laparotomy for an Ovarian Cystoma which had ruptured six hours before removal, with specimen. Dr. Kidd: Short Notes on a Case of Induction of Labour followed by Enucleation of Fibroid Tumour from Cervix. Dr. Purefoy: Report of the Rotunda Hospital for the year 1900-01. College of Physicians, 8.30 p.m.

MONDAY, FEB. 10th.

ROYAL COLLEGE OF PHYSICIANS.—Examination for Licence.
ROYAL COLLEGE OF SURGEONS.—Examination for License in Dietistry.
DUBLIN UNIVERSITY.—Final Medical Examination in Med. B.A.O. and M.A.O.

Appointments.

BELL, R. H., M.A., M.B., M.C. Cantab., Obstetric Tutor and Registrar to St. Thomas's Hospital, London.
BROWN, T. W. S., M.R.C.S., L.R.C.P. Lond., Certifying Surgeon under the Factory Acts for the Chatham District.
CHOLMELEY, W. F., F.R.C.S. Honorary Assistant Surgeon to the Wolverhampton General Hospital.
DICKMAN, H. G., M.B., M.S. Edin., Medical Officer of Health for the Urban District of Diss, Norfolk.
EDWARDS, G. M., M.B., B.S. Cantab., Certifying Surgeon under the Factory Acts for the Harrow District of Middlesex.
ELLIOT, S., M.D. Edin., Certifying Surgeon under the Factory Acts for the West District of Caithness.
FAIRBAIRN, J. S., M.B. Oxon., F.R.C.S. Eng., M.R.C.P. Lond., Assistant Obstetric Physician to St. Thomas's Hospital, London.
FISHER, CHARLES, M.B., B.S. Durh., M.B.C.S., L.R.C.P. Lond., House Physician to the City of London Hospital for Diseases of the Chest, Victoria Park, London.
FLETCHER, J. H., M.R.C.S., L.R.C.P. Lond., Medical Officer to the Ince Urban District Council.
GRAHAM, A. W., M.R.C.S., L.S.A., Medical Officer of Health for the District of Beaconfield and Dalrymple, Tasmania.
HARRIS, A. B., M.R.C.S., L.R.C.P. Lond., Medical Officer of Health for the Loughston Urban District.
HENSTED, B. H., M.R.C.S., L.R.C.P. Lond., Certifying Factory Surgeon for the Rural Districts of Whitechurch and Kingscote, Hants.
MACLENNAN, ALEX., M.B. and C.M., an Extra Honorary Surgeon to the Royal Hospital for Sick Children, London.
MORFITT, J. E. J., L.K.Q.C.P., L.R.C.S. Irel., Government Medical Officer and Vaccinator for Balranald.
PENFOLD, THOMAS C., M.B., M.S. Edin., Medical Officer of Health for the Hexham Rural District.

Vacancies.

Brecon Infirmary.—Resident House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, fire, and gas. Applications to the Secretary, 6, Bulwark, Brecon, South Wales, by February 19th.
Chester County Asylum.—Third Assistant Medical Officer. Unmarried, and not more than 30 years of age. Salary £180 per annum, with board, lodging, and washing. Applications to Dr. Lawrence, County Asylum, Chester, by February 12th.
Durham County Asylum.—Junior Assistant Medical Officer. Salary £140, rising to £180 per annum, with board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.
Kent County Asylum, Barming Heath, Maidstone.—Fourth Assistant Medical Officer and Pathologist, unmarried. Salary £175 per annum rising to £200, with furnished quarters, &c. Applications to Dr. F. P. Davies, Superintendent.
Lancashire County Asylum, Winwick.—Assistant Medical Officer. Salary commencing at £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent. (See Advt.)
Rainhill County Asylum.—Assistant Medical Officer. Salary £150 per annum, with prospect of an annual rise of £25 to £200. Applications to the Medical Superintendent. (See Advt.)
Salisbury: Fisherton Asylum.—Assistant Medical Officer. Unmarried and not more than 30 years of age. Salary to commence at £150 per annum, with board, lodging, and washing. Applications to Dr. Finch, the Asylum, Salisbury.
Suffolk County Asylum.—Second Assistant Medical Officer. Salary commencing at £130 per annum, rising to £150, with board, lodging, laundry, and attendance. Applications to the Medical Superintendent, County Asylum, Melton, Suffolk. (See Advt.)
Wolverhampton General Hospital.—1. Assistant House Physician; 2. Assistant House Surgeon. Appointments for six months. Honorarium at the rate of £75 per annum, with board, lodging, washing. Applications to the House-Governor by February 10th.

Births.

COPEMAN.—On Jan. 20th, at the Parade, Cowes, I.W., the wife of Alfred Heathcote Copeman, M.A., M.D., M.R.C.S., L.R.C.P., D.L., of a daughter.

Marriages.

DAVIES—SCOTT.—On Jan. 32nd, at the Church of St. Michael, Teignmouth, S. Devon, S. H. Battray Davies, M.R.C.S., L.R.C.P. Lond., to Mary Douglas, daughter of Lieutenant-Colonel Scott.

SMYTH—SMYTH.—On Jan. 32nd, at Rutland Square Church, Dublin, James Smyth, M.B., Clapham Junction, London, son of J. Smyth, Esq., Limerick, to Marion Moore, daughter of M. Smyth, Esq., Kilkenny.

Deaths.

GWYNN.—On Jan. 27th, suddenly, on board the Nile steamer "Furitan," near Cairo, Edmund Gwynn, M.D., of Ashdown House, Rosslyn Hill, N.W., late Medical Officer of Health for Hampstead.

STOCKTON.—On Jan. 25th, at King's Sutton, near Banbury, Arnold Stockton, M.R.C.S., L.R.C.P., youngest son of the late James Stockton, aged 29.

THE

DIAGNOSIS OF SCARLATINA. (a)

By JOHN MARSHALL DAY, M.D.,
Resident Medical Officer, Cork Street Fever Hospital.

THE diagnosis of scarlatina has now become a far more difficult matter than formerly, when the disease was of a severer and better marked type. From time to time cases are admitted to hospital in which the diagnosis is so very doubtful that a few remarks on the points on which to rely in coming to a decision may not be out of place.

The following may be related as a sample case: M. B., æt. 6, was admitted to Cork Street Fever Hospital suffering from whooping-cough. On the seventh day after her admission her temperature went up to 100°, she vomited, and her pulse was 132. There was redness on the pharynx, tonsils, and hard palate; there was a very slight browning of the flexures of the arms; no distinct rash could be observed on the body, except slight redness on the backs of the hands, the sides of the fingers, and at the flexures of the groins. The next day her temperature was 99°, pulse 128, and the child was apparently all right. The diagnosis then made was scarlatina simplex, but there was considerable doubt about the correctness of this opinion until it was confirmed by the onset of peeling on the sixteenth day, and on the twenty-second by distinct signs of nephritis, with blood and albumin in the urine.

The chief symptoms of scarlatina are vomiting, sore throat, elevation of temperature, frequent pulse, and rash.

1. Actual vomiting or a distinct feeling of nausea is nearly always present; in fact, I found this symptom prominent in over 90 per cent. of the cases admitted to Cork Street Fever Hospital. One must, however, discount it as a symptom in young people who are subject to attacks of nausea from various causes.

2. Children so seldom complain of sore throat that unless one follow the golden rule of always looking at the throat when examining a child, this symptom may be overlooked. One may find in severe cases that the patient swallows quite well, but the converse also holds good, and a simple relaxed throat is often accompanied by troublesome dysphagia. In examining the throat, get the child well wrapped up and facing a good light, when, if scarlatina be present, the red punctiform appearance on the pharynx, soft palate, tonsils and hard palate will be readily seen. The rash is not so distinctive on the inside of the cheeks as it is in the case of measles. In mild cases there is often a

peculiar dull, yellowish whiteness of the hard palate to be seen on the second day. I believe, however, that the rash on the hard palate is diagnostic, especially in cases of scarlatina *sine eruptione*.

3. At the commencement the temperature varies from 100° to 104°. It falls the next day, rising again in the evening, but not so high, and following this course generally becomes normal on the eighth to the tenth day. In mild cases it may become normal on the third day.

4. The pulse rate is more characteristic than the temperature, as even in the mildest case it is over 120, generally 140 to 160, and we find that, even after the temperature becomes normal, the pulse rate becomes higher than normal, for instance, a mild case of scarlatina, as M. G., æt. 6, on the third day temperature was 99°, pulse 108, and on the fourth day temperature was 98·6°, pulse 100.

5. The rash in scarlatina is never seen on the end of the nose, nor around the lips, i.e., in the circumoral zone. It is almost invariably out before the third day; I only once saw it delayed until the third day, and that was in the case of a child who was admitted to the hospital suffering from convulsions, but, after diligent packing the rash appeared and the convulsions ceased. It varies very much in degree; in the very mild cases there exists a fine punctiform rash on the tonsils, the hard and soft palates, and over the surface of the body where the skin is softest, such as the flexure aspect of the arms, the sides of the chest, the lowest part of the abdomen, the upper part of the thighs, and in the axilla. It can also be seen on the backs of the hands, the sides of the fingers, and on the dorsal aspect of the foot. When the elbow is flexed a browning along the folds of the skin is noted, and a similar condition is observed at Poupert's ligament, and also, but not so frequently, at the backs of the knees. This browning persists after the rash fades, and is present with red puncta on the lower limbs.

I shall now allude to a few other important points in relation to scarlatina before coming to the differential diagnoses.

Sweating is uncommon, but may be present in persons of rheumatic tendencies. The erythema often seen in such cases is generally of an evanescent nature, comes and goes, does not present the punctiform appearance, and is generally most intense on the chest.

The tongue in the early stages is coated, sometimes heavily, but later on the injected papillæ show through and it becomes stripped, and then the true "strawberry" tongue, with the prominent fungiform papillæ is well marked. One must especially distinguish cases where the tongue is covered with a slight fur, and the filiform papillæ are showing on the third or fourth day of the illness; a tongue with these appearances generally accompanies gastric catarrh.

When doubtful cases of scarlatina come under

(a) Read before the Royal Academy of Medicine in Ireland, Jan. 24th, 1902.

observation the course of examination I adopt is as follows:—First, the question is asked, Has the patient had scarlatina before? If the answer be in the affirmative, and the history of the attack be definite, I put scarlatina out of court, as I cannot call to mind definite, satisfactory, undoubted cases of a second attack of scarlatina accompanied by rash, although, of course, I admit one may have scarlatina *sine eruptione*, as a second attack. I then examine for (a) rash on the soft and hard palates, (b) browning of the flexures, (c) rash on the backs of the hands or the sides of the fingers, (d) stripping of the tongue, and (e) reddish spots, smaller and more acuminate than rose spots, on the lower limbs; these, with a history of vomiting or nausea, are, in my opinion, sufficient to justify a physician in mentioning scarlatina, and suggesting isolation.

Otorrhœa coming on without a definite cause is often the first symptom of scarlatina brought under one's notice, and when one meets such cases among children one should always remember scarlatina and look out for peeling. Such cases are, I believe, very infectious. I may pass by acute nephritis or dropsy as being a well-known sequela of scarlatina.

With regard to the important question of isolation, one must moreover remember that mild cases of scarlatina often do not show definite signs of peeling until three weeks after the onset of the rash, and then the peeling may take the form of a polishing of the tips of the fingers, a roughness at back of ears, a roughness of flexures of the joints and of the chest walls, with later on a stripping of the feet. The milder the case the longer it takes for desquamation to make its appearance. The desquamation in scarlatina is peculiar. It may commence on the sixth day, or be delayed until the eighteenth or twenty-first day. It is not a definite proof of scarlatina, but when one finds the tips of the fingers polished, and desquamation on the trunk and extremities which commenced in small pin-head points and has spread centrifugally, one may as a rule diagnose scarlatina.

I will now briefly consider the diseases with which scarlatina may be confounded, and will endeavour to put them in the order of frequency of mistaken diagnosis, viz.:—Rötheln, measles, septicæmia, urticaria, erythema, rheumatic fever, meningitis, enteric fever, and lastly, drug rashes.

Rubella or Rötheln.—Vomiting is not an initial symptom in this disease, and only an occasional coincidence. The rash is usually the first sign of the disease; it appears all over the face and body as reddish-brown spots, slightly raised, brighter than in measles, but not so bright as in scarlatina, or it simulates the rash of the latter, without its punctiform appearance or the browning of the flexures. In rötheln, as in scarlatina, the rash is present on the throat, similar in appearance to that on the trunk. The peeling of the tongue is absent. The glands in the post-sterno-mastoid and axillary areas are enlarged, and often also in the groins; still, this point is of no diagnostic value in dealing with children who are the subjects of chronic enlargement of the lymphatic glands.

In rötheln the temperature, as a rule, is only slightly elevated for the first twenty-four hours; still, I do not think much reliance can be placed on the character of temperature as a point in diagnosis. The pulse is not frequent as in scarlatina. The patient does not feel ill in proportion to the amount and colour of the rash. Slight peeling has been seen after the rash has disappeared, but it is not similar to that which I have described as characteristic of scarlatina. The illness may be regarded as at an end when the rash has disappeared.

Measles.—In measles there are the catarrhal symptoms, the appearance of the rash on the fourth day

on the face and upper parts of the body, and next day on the lower limbs; raised, reddish brown, crescentic spots, coalescing as the rash develops. The appearance of the rash on the buccal mucous membrane is typical. In some cases of scarlatina there may be a rash on the arms and chest very like measles, but, on further examination, one generally finds it to be quite characteristic on the lower part of the body and the lower limbs.

Septicæmia, or septo-pyæmia, may be ushered in with a rash which it is often impossible to distinguish from that of scarlatina. As a rule it is very intense on the arms and legs, and middle triangle of the body, is darker in colour, and does not present a punctiform appearance. Oftentimes one cannot distinguish the so-called scarlatina maligna from septicæmia.

Urticaria frequently presents a diffuse red rash over the body and limbs, but at places one can detect the characteristic wheals, while the rash is very itchy, rapidly comes and disappears, and often reappears.

Erythema is a very rare disease, and presents a sudden blush, confined mostly to the body, is not often seen on the legs or the arms, seldom on the hands, and is evanescent. There are no throat symptoms, and no constitutional disturbance.

Rheumatic Fever is a disease which may accompany scarlatina, or in which there may be a sore throat, sweating, reddish patches on the body and the arms, definite arthritis, or vague pains in the joints, as is especially the case when the disease occurs in childhood. The differential diagnosis in favour of rheumatic fever depends upon the absence of the circumoral and nasal white zone, of the rash on the hard palate, and upon the presence of stiffness of the muscles of the neck, and enlargement of the tonsils, and arthritis.

Meningitis.—I have seen cases of the malignant type of scarlatina mistaken for meningitis, and when one considers the extremely infectious nature of the former disease it behoves us to be very careful. In scarlatina there are great restlessness, semi-consciousness, a purple or dark red appearance of the throat, with slight swelling, great dryness of the tongue, cold, pinched extremities, with high internal temperature, and a dark brown or petechial rash in patches on the arms, chest, and groins. A history of sudden onset, frequent vomiting, the absence of retraction of the head, or of the abdomen, and peculiar odours off the breath, with the rash, &c., as above, makes the diagnosis easy if the two diseases be kept in mind.

Enteric Fever is often ushered in with vomiting and a sore throat, accompanied by a rash on the chest and abdomen, and sometimes on the arms. The diagnosis rests on the patient being more ill than one would expect from the character of the rash, on the appearances of the throat, on the temperature being very high, on there being a foul, faecal odour from the breath, and on the skin being moist and sweating. In a few days the abdomen becomes tympanitic, rose spots appear, and the diagnosis is confirmed. Still one must remember that there is a close relation between the two diseases, that they may be concurrent; that patients suffering from enteric fever are thereby rendered more liable to contract scarlatina, and, lastly, that in severe cases of scarlatina intestinal ulceration may be present, similar to that seen in enteric fever.

I remember an interesting fact which occurred some years ago in relation to these diseases. Enteric fever of a severe type broke out in a school near Dublin, and among the cases there was one girl, who, during the third week of her illness from enteric fever became covered with a red rash, chiefly confined to the trunk and thighs, and which very closely

simulated scarlatina; she peeled, but she did not convey scarlatina to any of the other patients in the ward. A year afterwards scarlatina broke out in the same school, and among those attacked this girl alone did not present a rash. She had scarlatina *sine eruptione*.

As regards the fourth disease (lately described by Dr. Clement Dukes), which we are accustomed to call r  theln with scarlatiniform rash. During the year 1897 there were in Dublin epidemics of r  theln, scarlatina, and measles concurrent, and although there was some difficulty at times in making a diagnosis, we were fortunate in not having an outbreak of r  theln in our scarlatina wards, and *vice versa*.

In that epidemic we treated the so-called two forms of the disease in the same wards, and I did not see any cross infection, although we detained the cases in hospital from seventeen to twenty-one days.

This so-called fourth disease is diagnosed from scarlatina by the absence of vomiting, the absence of rapid pulse, the occasional presence of enlarged glands, the presence of rash all over the face and body on the first day of the disease, and completely covering the body on the second day. It consists of pink spots, large but not so bright as scarlatina, with the absence of the brownish and the erythema seen in the latter disease, its rapid subsidence, and the absence of sequelae.

I may add that the disease is not always free from complications, as during the month of February, 1897, several children suffering from r  theln died from pneumonia and other complications.

I am of opinion that scarlatina, being a fixed disease, which changes its type slowly, is seldom, if ever, contracted twice. Measles is not so definite a disease as to severity of type, and may be contracted a second time.

R  theln, I believe, is more frequently contracted a second time, and the form of the disease may vary as regards the appearance of the rash.

In conclusion, I may lay down the following rules. Never attempt to diagnose disease from the character of a rash without seeing the whole of it; never attempt to make a diagnosis by artificial light, and, when in doubt, always act as if the more important disease were present, until its absence be certain.

PRELIMINARY REPORT ON "GAPES" OR "PIP" IN CHICKENS, AS DISTINGUISHED FROM DIPHTHERIA.

By FRAS. A. WINDER, B.A., M.B., B.Ch.

LATE in the year 1900 my attention was called to several papers appearing in the *British Medical Journal* on the subject of the "Connection between Epidemics of Diphtheria coincident with the Outbreak of Gapes among Chickens." Now this greatly surprised me, because ever since I was a child I had always believed—what any country person will tell you—that "gapes" or "pip" is caused by a small red worm which lodges in the chicken's windpipe; but as some members of our profession seemed to have some doubt on the subject, I thought it would be a profitable subject for investigation during the spring of this year, so I wrote round to all my country friends and relations to gain a supply of the needful materials.

From March to June, 1901 (the season of the year when this disease is prevalent), I dissected the bodies of ten chickens which were alleged to have died of this disease, as well as two which I had myself seen and examined while actually suffering from the "pip." The following are my notes on the subject:

When a chicken is seized with this disease it is

seen to "gape," that is, to stretch its neck and widely open its mouth, at the same time giving its head a shake as if desirous of expelling some foreign body which is obstructing its respiration. This gaping becomes more frequent. The chick becomes dyspnoic, unable to stand, refuses food, lies with its neck stretched out, and finally passes into a state of asphyxia, from which it never rallies, unless active therapeutic measures are undertaken.

Post-mortem all organs are found normal, except

FIGURE I.

Section of trachea (chicken No. 6) laid open to show worms in position. From life, (enlarged.)

the trachea and sometimes the lungs, which are frequently, but not always the seat of severe active congestion.

I will now give an account of these changes as found in one of the chickens which, I observed during her illness and afterwards dissected on April 30th, 1901.

"Chicken No. 6.—Female, age one month. General condition good, fairly nourished, but a lack of subcutaneous fat evident. All the organs healthy and normal except the respiratory. *Trachea*: About midway between the larynx and bronchial bifurcation was a mass composed of the bodies of six large, round, reddish-pink coloured worms, averaging in length from one to one and a quarter inches. They were lying lengthways in the trachea, and surrounded by thick semi-transparent glairy mucus. Two of the worms were free, unattached to the tracheal wall, only held in place by mucus. The other four were firmly attached by their bifurcated extremities.

The *lungs* were engorged with blood, almost pneumonic.

The *worms* vary slightly in length, the longest being slightly under one and a-quarter inches, the shortest over half an inch long.

The body is pink in colour and has a peculiar twisted appearance due to the distended uterus which runs the whole length of the worm's body. One extremity is sharp and pointed (the tail) the other is knobbed. This is the head and is armed with a large round sucker containing six chitinous teeth, leading to the mouth, and thence to a dilated pharynx.

About one-fourth of the worm's length from the head is seen a well-marked depression, which is the lateral vagina, and attached to this is a long, slender process about one-fourth of an inch or less in length, giving the worm a bifurcated appearance. This is the male worm firmly attached by its penis to the vagina of the female, his oral extremity being fixed by a sucker to the wall of the trachea of the chicken.

The female worm, as far as I have observed, lies free in the trachea (being held in her place by the male worm and by the glairy mucus which surrounds her), and has her head pointing towards the bronchi.

Almost the only structure visible in her body with the low power of the microscope is the enormously dilated spiral ovary, or rather uterus, commencing at the lateral vagina and extending down to the tail of the worm. It is usually filled to overflowing with small oval eggs, which seem to me to be emitted from the mouth and only sometimes from the vagina (as there appears to be no anus or other outlet) as this latter is blocked with the male worm, and I fancy that after copulation is accomplished the male worm dies, and the eggs are then set free, as those females which have no males attached are the largest, and have better developed embryos in them. However, I have seen eggs coming from the mouths of female worms whose vaginæ were fully filled up by their persistent husbands.

FIGURE II.

Female worm (enlarged) showing spiral uterus.

The eggs are to be counted in millions, and are oval and surrounded by a strong chitinous envelope.

The male worm is only one-sixth the size of the female, and rarely exceeds one-fourth of an inch in length. Both his extremities are knobbed, the head exhibiting a similar mouth with its sucker and chitinous teeth as the female. His head is firmly attached, being embedded in the tracheal mucous membrane, and requires a strong steady pull to detach it.

The other end is attached into the female vagina. I have never found a male worm free in the trachea.

These worms belong to the Nematoda, class strongylidæ, and are named by Cobbold—who gives a very brief account of them in his "Entozoa," page 84—*Sclerostoma Syngamus*.

Their life's history is unknown. The female worm lays her eggs by millions. These are probably coughed up by the chicken, or escape after its decease. Protected by their chitinous envelope, scattered by the wind, &c., they finally must enter some—so far unknown—host, in whose body necessary metamorphosis occurs. Chickens may be fed without danger either with the eggs of the worm or the worms themselves, and I myself only the other day devoured a cockerel who as a chicken had on three different occasions been fed on the worms and eggs without harm.

I hope next spring, when supplied with new material, to discover this "intermediate host," which is probably some insect—house fly?—or mollusc, and is in all probability picked up by the chicken on damp grass, as chickens confined in hen coops are less liable to contract pip, but are generally found to do so when they are allowed out after rain has fallen; in fact, country people say the disease is due to "damp feet."

Therefore, medical men may at once disabuse their minds that there is any similarity of cause between pip and diphtheria, except coincidence of time, and although I have made careful inquiries, I could not find any evidence to suppose that this worm is ever a parasite in a human subject.

NOTES ON THE ABDOMINAL AND PELVIC VISCERA IN ADVANCED PREGNANCY.

By J. G. MOORHEAD, M.D.,

Demonstrator of Anatomy, School of Physic, Trinity College

HAVING recently had an opportunity of dissecting the abdominal and pelvic viscera of a female subject, who was in the seventh month of gestation, I have thought it might prove of interest to bring before you to-night some of my notes.

I am more particularly led to do this because the subject was hardened by the injection of formalin. Although we have many accounts of the pregnant abdomen as observed in frozen sections, and in subjects prepared in the ordinary way, as far as I am aware no account has as yet been published of a case in which the viscera had been hardened *in situ* by formalin. The surface marking of the viscera is shown in the first photograph. In it it will be seen that the uterus extends well above the subcostal plane and is inclined to the right side, while the left ovary comes into relation with the anterior abdominal wall immediately above the inter-tuberculous plane and external to the left mid-Poupart plane. Lying just internal to the ovary is the left Fallopian tube. The upper markings represent the lower margin of the liver and of the stomach.

On opening the abdomen, the uterus is found to be not only inclined to the right, but also markedly rotated in its long axis, thus bringing the left ovary and Fallopian tube into the position I have described, while the right ovary and Fallopian tube lie posteriorly in contact with the cæcum. The upper margin of the uterus is at a point about ten inches above the symphysis pubis and is overlapped by the transverse colon and great omentum. The rest of the anterior surface was in contact with the parietes. Posteriorly it was moulded on the cæcum, right kidney, vertebral column, and the terminal part of the ileum. The peritoneum covering the uterus appeared to be of normal thickness. Traced down on the anterior wall it was reflected on to the back of the symphysis about half an inch above its upper margin, the point of reflection corresponding to the upper margin of the bladder. On either side the peritoneum was reflected on to the iliac fossa, this reflection corresponding to the base of the broad ligament. Posteriorly it is reflected on to the rectum at the level of the fifth sacral vertebra. It will be noticed that the posterior reflection is practically unchanged. Anteriorly it at first sight seems to be raised, but on consideration it will be seen that it still keeps its original relation to the uterus and only appears to be raised owing to the hypertrophy of that organ. The bladder does not hypertrophy and is thus left behind. As regards the broad ligaments, it was observed that the tubes lay in close contact with the uterus owing to the opening out of the layers of the ligament. Within the broad ligament the ovarian veins—particularly that on the left side—were found to be enormously dilated.

The greater part of the small intestine was found to the left of the uterus; a small amount extended, however, above the uterus and beneath the transverse meso-colon. The fossa left by the removal of the intestine is shown in one of the photographs.

Passing now to the pelvis we see that contrary to what might have been expected, the pelvic diaphragm is not in any way hypertrophied. Some additional support to the uterus appeared to be given by the obliterated hypogastric arteries. From

the upper and lower margin of these fibrous cords muscular fibres arose and passed on to the antero-lateral aspect of the uterus. These two supports, when viewed as a whole, presented the appearance of a hammock.

The bladder lay in relation to the lower portion of the uterus. It was triangular in shape and contained no urine. The apex was directed upwards, and lay behind the symphysis pubis; the base rested on the anterior wall of the vagina immediately in front of the place where the uterus pierced the anterior vaginal wall. The anterior aspect was convex from side to side and from above downwards, and the posterior aspect was concave and moulded upon the uterus. From the lower portion of the anterior aspect the urethra arose and passed downwards and forwards.

The intra-abdominal portion of the ureter presented the usual relations. That of the right side was obviously exposed to the pressure of the uterus. Crossing the external iliac artery the ureter proceeded downwards in front of the internal iliac artery and gradually passed to the inner side of that vessel, when it turned forwards lying about midway between the pelvic wall and the uterus; it was crossed by the uterine vein and artery, and then turning round the utero-vaginal junction, entered the bladder at each base angle. The right ureter enters the bladder at a point a little below and external to the point where the left ureter enters. The measurements were 26 mm. from the middle line on the left side, and 30 mm. on the right. The right entrance lay at a point 27 mm. below a line drawn from the upper margin of the symphysis to the upper margin of the great sciatic notch, and the left entrance 22 mm. below that line. These measurements give precision to the fact that the bladder shared in this obliquity and in the rotation of the uterus.

The vaginal plexus of veins which drains its blood into the internal iliac vein was enormously dilated. No enlargement of the bulb or clitoris was noticed.

The only other viscera that deserve notice are the kidneys. The upper margin of the right kidney extended to within half an inch of the last rib, and the lower margin to a point one inch above the iliac crest. It presented an upper facet in relation to the liver, and a lower facet in which the uterus rested. Over both facets the fatty capsule had completely disappeared.

The left kidney extended above to a point half an inch above the last rib, and below to a point an inch and a quarter above the iliac crest. Its relations and fatty capsule were normal.

It is thus seen that the right kidney was slightly displaced downwards. Inspection of the viscera seemed to favour the view that this was due to the anterior portion of the liver being hollowed out by the upward pressure of the uterus, and that its posterior part in consequence exerted an increased downward pressure on the kidney.

This displacement downwards, together with the atrophy of the fatty capsule may account for the greater frequency of movable kidney on this side.

Many of these facts agree with what has been previously recorded, while some few differ. I have purposely refrained from comparing my observations with those of others, as to do so would occupy too much of your time.

Burned to Death.

DR. DANFORD THOMAS held an inquest last week on the body of Dr. W. Grady, late of Dunnington Park Road, West End Lane, Hampstead, who was discovered in his room severely burned, and subsequently died at St. Mary's Hospital from shock consequent on the severe injuries received.

PINCE-NEZ IN OPHTHALMIC PRACTICE.

By ROBERT D. JOYCE, F.R.C.S.,

Ophthalmic Surgeon, Richmond Hospital.

WITHIN the last eighteen months a considerable number of persons wearing pince-nez have come under my notice complaining of epiphora or flowing of tears. In some cases two pairs of glasses were in use—pince-nez and ordinary spectacles—and only when the former were in use were the tears troublesome.

At first I supposed this to be due to the fact that, at least in some cases, the pince-nez frame did not sit quite straight on the face, thereby causing the wearer to see obliquely through the glasses. This would cause the lenses to act as cylinders which might produce a condition of irritation in the eyes—an asthenopia from wrong glasses in fact—associated with increased lachrymation.

However, on further investigation of the matter, I found that the trouble was caused by another condition altogether. This was, that the compressing force of the pince-nez dragged the tissues on either side of the nose to such an extent that the lower lid was actually pulled away out of position, and no longer lay up in close contact with the bulbar conjunctiva. The displacement of the lid with, of course, the inferior punctum, was small in amount, only about 0.2 or 0.3 mm., and thus easily escaped detection, all the more so as it has to be looked for while the glasses are on the patient's face. But even this small amount of eversion, this ectropion, is amply sufficient to cause the epiphora.

This is a very important matter, as such an eversion of the lid, present at first only when the pince-nez is actually on the face, will become permanent in a short time, and set going all the troubles associated with ectropion.

The surgeon, for the patient's sake as well as for his own protection, should guard against this by closely examining the pince-nez while on the patient's face, as this is a matter which the optician can hardly be expected to know much about. For if the epiphora is set up by wearing the glasses, the patient will very naturally conclude that the lenses are "wrong," and will thus associate the surgeon, rather than the optician, with the fault.

In a large proportion of cases, pince-nez will sit well on the face, and be a "good" fit as far as the optician is concerned; but in a certain number of these, they are really unsuitable and injurious for the above reason.

The surgeon should see the frame on the patient, if possible before the lenses are fitted into it, and also see that the spring is as weak as is compatible with steadiness. Some few cases will be noticed in which it is not possible to fit with pince-nez without causing this ectropion.

Paris Clinical Lectures.

TREATMENT OF CROUP.

By DR. RENAULT,

Professor at the Faculty of Medicine of Paris.

IN cases of so-called croup we must observe the same rules as for diphtheria, at any rate so far as concerns injections of serum. I may remind you that, as far as the serum itself is concerned, we need not trouble ourselves about the more or less clearness of the liquid, but we must always be careful to remark its odour, rejecting all serum with a pronounced disagreeable odour. In the case of children

you should make the injection in the flank, as there the cellular tissue is sufficiently lax to admit a large quantity of serum without causing undue pain. It is best to use the syringe of Roux or of Debove, which has the advantage of being easily sterilised. This syringe is furnished with a rubber tube which is of some importance, because if the child struggles and cannot be kept quiet, the tube being mobile, the needle once inserted under the skin remains fixed in position and you can proceed without hindrance. Before using it you will, of course, boil your instrument, but I would suggest that you should see that it works all right before the sterilising process, because it is annoying to find after all your trouble that the instrument does not work. These preliminary steps having been taken to give satisfaction, you next proceed to thoroughly cleanse the skin. For this purpose we employ a solution of perchloride of mercury, carbolic acid, or simply boiled water and soap.

The injection should be made slowly, so as not to distend too rapidly the cellular tissue. When terminated a piece of cotton-wool dipped in collodion and a bandage are all that is necessary.

A word as regards the quantity of serum to be injected. In the first place I would advise you to pay more attention to the opportune moment of the injection than to the quantity of the liquid you elect to use. It must be remembered that the various little accidents imputed to the serum are the same with small as with large quantities. Cases of death have been attributed to the serum, but in reality they were not due to this agent. You may, however, meet with cases in which, after the injection, the temperature has run up and the general condition of the patient has seemed to become worse, but after a few hours the temperature falls and the malady follows the usual course.

As regards the quantity of serum to be used, you should inject as many times as may be necessary to bring about an improvement in the symptoms: the temperature, the state of the pulse, the extent of the false membranes and the condition of the glands, &c. But in the case of croup a larger injection must be made than in that of ordinary diphtheria, so as to be sure that a sufficient dose has been given. If, for instance, you give ten c.c. in diphtheria, you can return a few hours later to see if the false membranes have diminished, and, if not, you can repeat the injection. You have, in fact, plenty of time before you. Whereas in croup there is immediate danger, asphyxia by laryngeal obstruction being imminent, consequently a large dose must be given forthwith. I recommend for a child under five years twenty grammes (3vj), and over that age thirty grammes (3j). In diphtheria you will only inject at the outset 10 to 20 grammes respectively. When you return to see the child you will repeat the injection, but at half the dose, and repeat it as many times as may be necessary.

If the attack of croup is not very acute, if there be no abdominal suction nor attacks of suffocation, nothing is required beyond the injections. But if those complications be present, the question of intubation or tracheotomy presents itself. Simple or intermittent abdominal retraction does not, however, render the use of the tube absolutely necessary. You must be guided by the condition of the little patient. If he is obviously exhausted by the labour of respiration, that is to say, if he is in a somnolent condition, if his pulse has become extremely rapid, if his face becomes a little cyanosed showing that the heart is failing, then you will have to act promptly and not delay, as otherwise the child may succumb before your next visit.

And now as to the choice of operation. Both in-

tubation and tracheotomy have their special advantages. Those of intubation are obviously that of not entailing a cutaneous wound followed by a cicatrix, which, in young girls at any rate, is unsightly. It has been urged that tracheotomy, moreover, is not a bloodless operation, but the two or three drachms of blood that a child loses during this operation can never be of much importance.

You must base your choice on the necessities of the after-treatment. In the case of tracheotomy a capable person must be put in charge to change the inner canula; as to the outer canula, you must change it yourself every twenty-four hours. With the tube, on the contrary, the instrument may get blocked suddenly or gradually, and in such case it must be withdrawn and reinserted, a manoeuvre which the medical attendant alone can carry out. The only reason which seems to militate in favour of the tube versus tracheotomy is the place where you have to perform the operation. If at the hospital you will probably give the preference to intubation, and in forty-eight hours you will remove it, the treatment being at an end; whereas after tracheotomy a fortnight or more may be necessary, and a tear remains. Be that as it may, one thing is certain: where the tube is employed you will have to keep the patient under close personal observation, either by yourself or your assistant; whereas in the other, any intelligent person can keep the canula free. The complications of diphtheria are of two kinds: paralysis of the fauces and myocarditis. They make their appearance usually towards the third week. Fortunately the former is not very serious, but the latter, or paralysis of the heart, is of greater significance, for in seven or eight days the child may recover or die.

The paralysis of the throat will get well without any treatment, but as the parents might attribute your abstaining from prescribing to ignorance, you will do well to order a few drops of tincture of nuxvomica. For the myocarditis you will keep the child in bed for at least three weeks, so as to secure rest for the heart. All emotion must be avoided and a milk diet prescribed, with counter irritation over the heart and stimulants given: syrup of ether, Hoffmann's anodyne, subcutaneous injections of caffeine, &c.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF ANATOMY AND PHYSIOLOGY.

MEETING HELD AT THE ROYAL COLLEGE OF SURGEONS,
ON FRIDAY, JAN. 31st, 1902.

Professor CUNNINGHAM, the President of the Section,
in the Chair.

ON taking the chair, the PRESIDENT thanked the Section for his election. He then briefly reviewed the work done by its members during the nineteen years of its existence, work which reflected great credit on the Section both for thoroughness and originality. It seemed to him to have been marked by three great waves, which he would take the liberty of naming—the morphological wave, the cerebral wave, and the visceral wave. One of the first papers produced at the Section, and he thought the first printed, was that very excellent contribution of Mr. Abraham on the frequency with which the *musculus sternalis* was found in encephalous fetuses. The paper was the outcome of intimate knowledge of human and comparative anatomy and accurate observation. Throughout Europe it awakened interest, and by that single paper the Section at once became the centre of interest to all anatomists. Discussions throughout the world's medical schools took place on the subject, and the views of the Dublin school

were opposed strongly; but he was glad to say that the two papers of Eisler, of Berlin, and Wilson, of Melbourne, support the views put forward by Mr. Abraham in that room. The cerebral wave was created by the remarkably beautiful exhibition of cerebral photographs prepared by Professor Fraser. For their general usefulness and beauty of finish they have never been excelled. Professor Fraser has also been engaged on the study of the topography of the sinuses of the cranium, and his work in this direction has become a necessity, not alone to the anatomist, but also to the practical surgeon. Under his (Professor Fraser's) hands the cerebral wave had attained its highest point. The visceral wave included the splendid work done by Professor Symington, of Belfast, and that of Professors Fraser, Birmingham, and others. He hoped the Section would continue to do good work, and he thought the younger men might produce a collective investigation report. The production of such demanded hard work, constant work—the enthusiasm of youth.

Professor Symington having been called to the chair, Professor CUNNINGHAM read a paper on "The Inferior Parietal Lobule." It had become the practice of a considerable number of Continental anatomists to form an opinion of the sex, race, intelligence, and capability of the individual from an examination of the inferior portion of the parietal lobe of the cerebrum. He could not accept these views, although they were supported by a considerable amount of ability, and by the exhibition of a series of cerebral specimens of comparative anatomy and the cerebra of human beings—knaves, fools, and philosophers. (Here a number of screen pictures were shown.) A theory put forward and supported by Retzius, Guzman, Hausman and Euge could not be lightly thrust aside without consideration, and it is to be borne in mind that the inferior lobule is late in development in the human being, and may fairly be considered as engaged in the higher function of cerebration; withal he is driven to a diametrically opposite conclusion. In a certain series of brains specially prepared to show the development of this lobule from those of the foetus to those of advanced life, he cannot see in many of them that the higher intellectual powers have always been associated with a larger and more complex gyrated lobule. Professor Cunningham exhibited a series of screen pictures of cerebra in support of his views.

Prof. COFFEY said he considered Prof. Cunningham's demonstrations of the surface anatomy of the inferior parietal convolutions a most interesting supplement to Flechsig's work on the development of association fibres in the same area. How far such an area could be termed a place of intellectual operations in the brain depended very much upon the exact signification to be attached to the term intellectual. Intellect itself, he thought, was a question of capacities not necessarily associated with any area, but deriving the matter upon which it emanated, and through which it manifested its activities, from both the primary sense areas and the association centres alike. He thought that the slides shown bore out his view that these so-called intellectual areas in reality had to do with the conscious functions which were intermediate, so to speak, between primary sense representations in the brain and the higher psychical capacities. The latter had no place representation whatever.

Professor FRASER cannot look on the brain in the same way. The mere surface scratching on the outside of the sac conveys nothing to him. A smooth brain has got all its lobes. The brain of a fanatic is quite as complicated as that of a mathematician; and the man in the street may have a brain as complicated as the ablest.

Professor SYMINGTON was very glad to hear Professor Fraser's remarks, his statements conveyed a great deal of truth, they knew very little as yet of localisation of function. But he cannot go the whole way with Professor Fraser, the human brain has a differentiation of function which is not to be found in that of fishes. Like Professor Cunningham, he is doubtful of the localisation of special intellectual ability in the inferior

lobule of the parietal lobe. He is thankful to Professor Cunningham for having brought the matter forward, and with him he agrees that the better developed brain is possessed by the highly civilised.

Professor CUNNINGHAM thanked them for the interesting discussion his paper elicited, and he felt it due to Professor Fraser to say that with a great deal of what he said he fully agreed.

Dr. ALLWORTHY's paper on

CONGENITAL MALFORMATION OF THE HANDS.

was, in the absence of the author, read by the Secretary of the Section.

The photograph and radiograph taken by Dr. Allworthy are of a man's hands, *æt.* 30, who was a seven months' twin. All the bones of the middle finger are absent in the right hand. The first phalanx of the left index finger evidently developed across the palm of the hand, as shown in the radiograph, and its pressure wedged the bones of the second and third fingers into each other, so that they became united.

Professor COFFEY then read his paper.

MICROSCOPICAL PREPARATIONS OF CERTAIN "NERVE ENDINGS IN THE AUDITORY TRACT,"

with a series of microscopic preparations.

Professor Coffey demonstrated the three typical forms of endings of the cochlear nerve in the *pons cerebri*, calyces, tree-root endings and encapsulating fibres. The specimens were stained after the manner of Cajal, of Madrid, and Wehl, of Leipzig.

Professor FRASER did not think the dark staining satisfactory. One never felt certain that he was looking at nerve fibre, as the finer vessels simulated fibres. He preferred copper staining, it gave a clearer better view of the fibres, but it did not keep for more than forty-eight hours. The splitting of the fibres into ascending and descending fibres he had recognised and demonstrated as far back as 1886.

Professor CUNNINGHAM feared that few of them had worked much on nerve endings, and he congratulated Professor Coffey on his excellent paper and beautiful exhibits.

Professor BIRMINGHAM read a note on

STOMACH CHAMBER.

About two years ago, in a paper contributed to the *Journal of Anatomy* he introduced the terms "stomach chamber" and "stomach bed." For these he had to encounter a good deal of quizzing, but he thought the terms helpful and stuck to them. It was his object tonight to make plain to the Section that there is a "stomach chamber" and a "stomach bed," for this purpose he brought a specimen hardened *in situ* by formalin and gelatin. The anterior abdominal wall having been removed, the stomach which was distended and hardened, and had been cut free at both extremities was lifted out showing a distinct chamber, bounded superiorly by the diaphragm, and inferiorly by the small intestines, pancreas, upper extremity of the kidney, and transverse mesocolon. This chamber, the viscous fills when distended; when in a condition of contraction, a portion of the colon presses up in front of the viscous into the chamber. In the healthy male adult, he finds that the stomach projects downwards, at an angle of 45°, inwards and forwards. When distended its pyloric extremity tilts upwards, and its oesophageal opening is not directly on its lesser curvature, but opens on the anterior surface. Tight-lacing displaces the viscous and alters its relations. A contracted stomach may easily be mistaken for a portion of intestine.

Professor SYMINGTON quite agreed with Professor Birmingham that the stomach projects forwards and downwards, and that it does not in the adult hang vertically, as might be seen from his article on the stomach in "Quain's Anatomy." But he cannot see any advantage in the term "stomach bed" or "stomach chamber." He heartily congratulated Professor Birmingham on his demonstration.

Professor CUNNINGHAM agreed with Professor Birmingham that the titles "stomach bed" and "stomach chamber" were useful and helpful. The transverse

mesocolon does divide the abdominal cavity into a gastric and an intestinal region.

Dr. T. G. MOOREHEAD read notes on the abdominal and pelvic viscera in a case of advanced pregnancy.

The specimen was hardened *in situ* by the formalin process and photographed. The subject had reached the seventh month of pregnancy, and it was, probably, the first occasion of such a specimen being photographed for exhibition. The uterus extended well up into the abdomen and inclined to the right side, the left ovary came in contact with the anterior abdominal wall. The uterus was also rotated on its long axis, which brought the right ovary in contact with the cæcum. The upper margin of the uterus lies at a point two inches above the symphysis pubis, and is overlapped by the transverse colon and great omentum.

Professors Cunningham, Symington, Fraser, and Birmingham congratulated Dr. Moorhead on his unique and splendid specimen, and the excellence of his paper, which left nothing to be added to its fulness.

Professor FRASER exhibited the abdominal cavity of a female subject between 50 and 60 years of age, obtained in the dissecting room, in which the descending limb of the early umbilical loop had neither turned to the left nor adhered to the posterior abdominal wall. The colic or ascending limb, however, turned to the right passing across the front of the second portion of the duodenum and to its usual position in the right iliac fossa, and had adhered to the posterior abdominal wall along its whole length in the usual manner. This condition resulted in the duodenum lying wholly to the right side and being formed by only its first ascending and its second or descending portion, the transverse and terminal ascending as well as the duodeno-jejunal flexure being absent. The coils of the jejunum lay to the right and behind the mesenterium commune, being in this way concealed from view on turning up the first omentum and transverse colon. The coils of the ileum lay to the left and in the pelvic cavity. On turning the coils of the ileum upward, the finger could be placed on the origin of the superior mesenteric artery from the aorta which ran freely out in the mesenterium commune.

Owing to the lateness of the hour remaining papers were taken as read.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, FEBRUARY 5TH, 1902.

PETER HORROCKS, M.D., President, in the Chair.

SPECIMENS.

Dr. AMAND ROUTH showed (1) an ovarian dermoid removed by posterior colpotomy. He raised the question whether ligatures on the pedicle should be left long as in vaginal hysterectomy, and whether the peritoneal opening should be sutured. (2) A uterus removed by supra-vaginal hysterectomy at the end of 8½ months of pregnancy on account of a large fibroid tumour impacted and adherent in the pelvis.

The PRESIDENT said that for some years he had not used ligatures for vaginal hysterectomy, but forceps; he did not suture the peritoneal opening, but left in a plug of gauze. It was now, he thought, generally agreed that it was better not to close the vaginal vault. It did not seem to him advisable to remove a dermoid through the vagina if it required tapping; for dermoid contents were very irritating to the peritoneal cavity, much more so than the contents of ordinary ovarian tumours. He had not been able to demonstrate the presence of any micro-organism in dermoids, but had found the margins of the abdominal wound in a condition of intense irritation when they had been contaminated by dermoid contents.

Dr. CHAMPNEYS said that he was much opposed to the closing of the vaginal vault. Like the President, he had discarded the ligature in vaginal hysterectomy; and in the case of the removal of cysts by posterior colpotomy he had adopted the plan of avoiding the ligature and of placing forceps on the pedicle. There was then nothing left to come away, and the forceps made an excellent drain. He thought that Dr. Routh

had adopted the right treatment in his second case; it made all the difference whether a fibroid was attached to the anterior or the posterior wall of the uterus. If in the anterior wall it could often be pushed up, or even became spontaneously pulled up; but a relatively small fibroid in the posterior wall might cause considerable obstruction.

Dr. HERMAN thought it was disadvantageous to take away such a tumour as a dermoid through the vagina. One thing against it was that the pedicle had to be drawn down so tight that it was difficult to make sure that the ligature would not slip. He did not see the advantage of draining if the case was aseptic, nor did he see any drawback in the ligatures under these circumstances.

Dr. ROUTH, in reply, said that he thought that a forceps on the broad ligament in removing a cyst was rather unsurgical. With regard to tension on the pedicle while tying it, this could be minimised by the plan which he always adopted when possible, namely, by retroverting the uterus so that the ligature could then be applied with ease.

Mr. J. BLAND-SUTTON showed (1) a pregnant tube diagnosed before rupture; the main point of interest was the large size the tube had attained without giving way. (2) A specimen from a case of tubal abortion. The patient was æt. 32, and had had one child eleven years previously. Menstruation was regular till July 5th of last year, when she missed. Five days later she went for a bicycle ride, and had a sharp attack of collapse. From reading about the symptoms she came to the conclusion that she had a tubal pregnancy. Nevertheless she went for another ride, and had another attack of collapse. On seeing her, he came to the conclusion that her diagnosis was correct, and he operated. A quantity of free blood was found in the pelvis. In the ampulla of the tube was a large clot, which was not the mole. Fragments of placenta were, however, found entangled in a mass of clot hanging from the end of the tube.

Dr. HERMAN asked whether there was any special clinical history in the first case, for the layers of clot were of a different colour suggesting the occurrence of a succession of hæmorrhages.

Dr. LOCKYER asked whether it was not unusual to find such a large amniotic cavity as was present in the first case?

Dr. ROUTH asked whether Mr. Bland-Sutton could say why the amniotic cavity was always so much larger in the uterine than in the tubal mole; and also why a hydatid mole was never found in the tube?

Mr. BLAND-SUTTON, replying, said that he thought he remembered seeing a case recorded of a hydatid mole in a tube, and it was reported that the patient developed a deciduoma malignum in the tube later on. He had not seen a case himself. In reply to Dr. Herman's question, there was more pain in his first case than in almost any other case he had known; it might have been due to the repeated hæmorrhages. He did not know any reason for the smaller size of the amniotic cavity in tubal moles.

ANNUAL MEETING.

The Reports of the Treasurer, Honorary Librarian, and Chairman of the Board for the Examination of Midwives were read and adopted.

The PRESIDENT then delivered the Annual Address, in which he referred to the proposed alterations in the laws, and reviewed briefly the work of the previous year.

A vote of thanks to the President for his address was carried by acclamation.

The officers nominated by the Council for 1902 were pronounced duly elected as follows:—

President: Peter Horrocks, M.D. Vice-Presidents: John W. Byers, M.A., M.D. (Belfast); Edward Malins, M.D. (Birmingham); John Phillips, M.A., M.D.; *Herbert R. Spencer, M.D. Treasurer: *Francis Henry Champneys, M.A., M.D. Chairman of the Board for the examination of midwives: W. R. Dakin, M.D. Honorary Secretaries: Amand Routh, M.D.; *Montagu Handfield-Jones, M.D. Honorary librarian: *Robert Boxal

M.D. Other Members of Council:—*Comyns Berkeley, M.B., B.C.; Henry Briggs, M.B. (Liverpool); Thomas Vincent Dickenson, M.D.; Charles Owen Fowler, M.D.; *Charles Arthur Goulet; Walter Spencer Anderson Griffith, M.D.; *David Berry Hart, M.D. (Edinburgh); *Arthur Corrie Keep, M.D., C.M. Edin.; Arthur H. N. Lewers, M.D.; Thomas Robert Lombe, M.D. (Torquay); *William Rivers Pollock, M.B., B.C.; *Harry Campbell Pope, M.D.; *Edward Reynolds Ray; William London Reid M.D. (Glasgow); William Japp Sinclair, M.D. (Manchester); *Thomas George Stevens, M.D.; *Francis T. Taylor, M.B.; John William Taylor, F.R.C.S. (Birmingham). Those gentlemen to whose name an asterisk is prefixed were not on the Council, or did not fill the same office last year.

The following alterations in the laws were proposed by the Council and adopted by the meeting:—

Chap. I., Sec. 3.—Instead of "All medical men, possessing a qualification registrable in the United Kingdom, shall be eligible for election as ordinary Fellows of the Society," read "All medical practitioners possessing a qualification registrable in the United Kingdom shall be eligible for election as ordinary Fellows of the Society."

Chap. XVI., Sec. 7.—Instead of "All papers read before the Society shall be considered the property of the Society. If published elsewhere they shall not appear in the 'Transactions.' Papers rejected for the 'Transactions' shall be returned to the authors, and shall no longer be considered the property of the Society," read "All papers read before the Society shall be considered the property of the Society; but authors of papers accepted for reading before the Society are at liberty to publish them in any scientific periodical after they have been read, provided that acknowledgment of the fact of their having been read before the Society is made in such periodical."

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD JAN. 30TH, 1902.

MR. RUSHTON PARKER, President, in the Chair.

GALL-STONES WITH CHRONIC INTESTINAL OBSTRUCTION.—Dr. A. C. WILSON described a case in which many diagnoses had been given by various physicians in Liverpool and London. Eventually an exploratory operation revealed gall-stones in the gall-bladder and duct, which were removed, also a curious mass in the intestine which was not dealt with.

MR. R. W. MURRAY described the operation he had performed in Dr. Wilson's case. He believed the lump in the intestine to be an impacted gall-stone. In order to deal satisfactorily with this, he thought it would be necessary to short circuit the gut, and would not advise further operation unless the suffering of the patient became unbearable.

The President, Dr. Macfie Campbell, and Dr. Gill commented upon the case, and Dr. WILSON replied.

INTESTINAL ANASTOMOSIS.—MR. R. W. MURRAY exhibited a boy, *æt.* 13, upon whom he had operated for an artificial anus in connection with the small intestine, complicated with considerable prolapse of the gut. Three years previously the boy had been operated upon for intestinal obstruction, a portion of the small intestine, probably about three feet from the ileo-cæcal valve being brought to the surface and opened. Prolapse of the bowel resulted, and for three years all faecal matter escaped from this opening in the small intestine. When first seen by Mr. Murray in May last the child's condition was pitiable; he was wasted, anæmic and carried his prolapsed gut in a bag attached to his waist. In July Mr. Murray opened the abdomen, and attached the working end of the small bowel to the transverse colon, end to end. The large gut was much collapsed, and as it had been lying fallow for three years there was some doubt as to whether it would resume its function. The result, however, was very satisfactory, the bowels acting naturally forty-eight hours after the operation. The general health and comfort of the patient have greatly improved, although there is still a

portion of unused bowel prolapsing from the original wound.

THE PHYSICS OF THE MITRAL REGURGITANT MURMUR.—Dr. BRADSHAW said that hitherto no thoroughly satisfactory explanation was forthcoming of the fact that the murmur was heard most plainly at the apex of the left ventricle. He suggested that it was brought about in the following way:—The fluid vein in the left auricle set up sonorous vibrations in the still parts of the blood behind the mitral valve. The valve being a thin membrane capable of vibrating, transmitted these vibrations to the blood in the ventricle, which conducted them to the apex, the part nearest the chest wall. He was making experiments with models to ascertain how far this kind of transmission was possible, but so far he had not succeeded in exactly reproducing the conditions artificially, as the construction of such a model involved considerable mechanical difficulties.

Dr. Barr spoke, and Dr. BRADSHAW replied.

Dr. STOPFORD TAYLOR read a paper on the

TREATMENT OF CANCEROUS AFFECTIONS OF THE SKIN BY MEANS OF THE X-RAYS,

illustrating his remarks by lantern slides and patients. Case 1.—Rodent ulcer involving right side of nose, lachrymal canals and eyelids, in patient, *æt.* 82. Case 2.—Rodent ulcer on left cheek, implicating outer canthus and eyelids, in patient, *æt.* 64. Case 3.—Epithelioma or lupus erythematosus affecting the whole surface of the nose in patient, *æt.* 59. Microscopical confirmation of diagnosis. Treated by scraping, followed by X-ray applications. Case 4.—Large rodent of left side of scalp and pericranium in patient, *æt.* 78. The foregoing cases were of such a nature as to be beyond operative interference, or relief by any other known method. The treatment in the first three cases resulted in complete healing of the ulcerated surfaces, with the formation of the most perfect scar tissue, and disappearance of all traces of disease. In the fourth case as the pericranium was involved, only partial healing took place, but the wearying pain which usually attends rodent ulceration was much relieved. As a result of the treatment, Dr. Stopford Taylor arrived at the following conclusions: 1, That the rays were especially indicated in all inoperable cases of cancer of the skin; 2, that the best results were obtained when the disease was confined entirely to the soft part; 3, that owing to the complete relief of pain, and a superior cosmetic result obtained patients too readily assumed that they were well, and neglected to attend, and thence recurrence might occur from failure to complete treatment, and 4, that the use of X-rays was no obstacle, but a valuable aid to the other methods.

MR. ARTHUR WALKER thought the action of the X-rays on rodent ulcer was not due to their escharotic power, but to some influence which, as it were, turned the scale of growth in favour of the healthy tissues, thereby enabling them to destroy and absorb the malignant cells. In cases treated by the X-rays at the Northern Hospital he had noticed that the rolled edge remained in the skin after the ulcer had healed, and then gradually disappeared, and in one case in particular, of recurrence in which further operation was refused, the skin was never broken, but the new growth slowly became absorbed under the influence of the rays.

Dr. GULLAN congratulated Dr. Stopford Taylor on the cases, and noted especially the excellent supple character of the skin, and the splendid condition of the scar tissue.

The President, Drs. Alexander, Leslie Roberts, and Mr. Newbolt spoke, and Dr. STOPFORD TAYLOR replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

THE December and January meetings of this Society were, according to custom, held in Manchester, and the last meeting for 1901 was the occasion of a particularly interesting Presidential Address by Dr. GRIMSDALE, of Liverpool. His subject was—

PROGRESS IN SURGICAL METHODS,

and his treatment of it was of interest not only

to gynaecologists, but to all surgeons. Progress in surgical methods was regarded as having seen three stages or periods:—(1) The pre-antiseptic or open method period; (2) the antiseptic or drainage-tube period; and (3) the aseptic or period of complete closure. In the first period suppuration was thought inevitable, and wounds were left open. In the second suppuration was expected, and a vent was left for the exit of pus. In the third the presence of suppuration denotes failure; it is not expected, and wounds are completely closed. Dr. Grimsdale illustrated the first period by references to the work of Alanson at Liverpool, about 100 years ago, and he quoted some of that writer's "Observations on Hospital Management," which show the genius of the man and the difficulties which surrounded the surgeon of those days. Many of his suggested regulations might have been written to-day. Others are more primitive. For instance, "Let the nurse of each ward be liable to a fine if some of the windows of her ward are not kept open during a stated number of hours every day," and "Let the nurses see that every patient's hands and face are washed every morning, and their feet once a week." The main feature is the importance attached by Alanson to the part played by the air in spreading infection. We think less of the air and more of the hands—we think less of infection and more of contagion. This is really the chief difference between the work of the present and that of 100 years ago. In the next, or antiseptic stage, "wounds were douched and swilled with antiseptics, and sometimes filled up with iodoform. In the aseptic method there is nothing put into the wound to irritate it or to help it to heal; the object is to keep out all that is detrimental to healing." The advance from the second to the third stage is marked and measured by the ease of recovery after operations. Dr. Grimsdale now uses no antiseptics whatever during operations, and the dressings are sterile, not antiseptic. The skin of the patient and the hands of the operator are prepared with antiseptics which are then put aside. His results were displayed by two composite charts. One chart compares the mean pulse curve obtained by combining the pulse curves of forty patients who had abdominal sections performed under antiseptics with the combined pulse curve after forty sections performed without antiseptics. The "aseptic" curve shows a distinctly better and more even recovery than the "antiseptic" curve. The other chart deals with "aseptic" and "antiseptic" temperature curves from the same eighty patients, and also demonstrates a less febrile recovery in the cases in which no antiseptics were used. In making the composite charts, the records of the forty individual charts of each series were added together and divided by forty, to give the mean. There were two observations daily for three days before and a week after operation. Apart from these plain results, there was less pain, less flatulence, and greater general comfort in the aseptic than in the antiseptic series. It is to be hoped that Dr. Grimsdale's address may lead many to be content with cleaning their hands and boiling their instruments, and to refrain from irritating their wounds with antiseptic lotions and dressings. The Presidential Chair of the Society will be filled for the present year by that genial and popular Manchester member, Dr. Sam Buckley. The Secretaryship remains for the present at Leeds, in the efficient hands of Dr. E. O. Croft.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY. MEETING HELD JAN. 30TH, 1902.

The President, Dr. C. H. WILLEY, in the Chair.

DR. BURGESS showed a young woman with bifid uvula and greatly hypertrophied false cords. The true cords looked like folds of mucous membrane, and the voice was produced by the false cords. The patient's mother had a cleft palate.

Dr. BURGESS also read notes (1) of a case of ataxic paraplegia, due apparently to lead poisoning; (2) a severe case of transverse acute myelitis in which the legs were flaccid, the knee-jerks absent, and there was

complete loss of power and sensation for over a fortnight. The patient was able to walk out of the hospital two months after the onset of the illness.

Mr. PRY-SMITH showed a boy, *æt.* 14, on whom he had performed Peters's operation of extra-peritoneal transplantation of the ureters into the rectum, for congenital extroversion of the bladder. Rectal tolerance of urine had been soon established, and the boy's condition had been greatly improved during the four months that had elapsed since the operation.

Dr. PORTER showed specimen of cerebral tumour, and read notes of the case.

Dr. A. J. HALL read a paper on "The Varieties of the Ringworm Fungus, their Clinical, Cultural, and Microscopical Characteristics, with some Observations as to their Distribution in the Sheffield District." The paper was illustrated by numerous microscopical preparations, cultures, photographs, &c.

Lunacy Department.

LUNACY IN LANCASHIRE.

THE new asylum erected by the Lancashire Asylums Board at Winwick has now been formally opened, and the patients will be drafted there without delay at the rate of 100 per week. It will meet a badly felt want, for the accommodation both at Whittingham and Prestwich has been in a congested state, and it will relieve the pressure for accommodation which has unfortunately prevailed for some time. Winwick Asylum, which is chiefly intended for chronic cases, provides accommodation for 2,000 patients, 1,000 of each sex, and also accommodation for the necessary medical and ordinary staff. Ample provision has, therefore, been apparently made for the insane poor of Lancashire for some time to come. This new asylum has been erected on the pavilion system, the administrative block being in the centre and the different wards on each side connected by corridors. The site, formerly known as Winwick Park, cost £21,000. The total sum already expended, exclusive of furniture, reaches £382,955, but after the asylum has been completed and fully equipped, it is expected these figures will be increased to £400,000, or £200 per head, a fairly moderate sum. Ornamentation has been almost dispensed with; electric lighting has been installed throughout, and the necessary machinery is driven by electric motors. Such conditions now exist in many asylums, and this provides abundant proof of their efficiency. A church capable of seating a congregation of 800 has been built in the grounds and twelve cottages, and two lodges have also been erected. The Committee are to be congratulated on the satisfactory result of their labours, and they have wisely kept in view some essential points in the construction of an asylum, which are apt to be overlooked, *viz.*, efficiency and stability, coupled with economy.

SCARLET FEVER AT HEREFORD COUNTY ASYLUM.

THE medical superintendent has furnished a Hereford Times reporter with a detailed account of a serious outbreak of scarlet fever at Burghill Asylum. In describing the outbreak, the origin of which they have unfortunately failed to trace, he says several cases of sore throat occurred, and subsequently, symptoms of scarlatina developed. Ten nurses and three female patients have in all been affected, but a great number of sore throats of an infectious character have been prevalent among the patients for the last two months, and these he considers, as probably being technically mild cases of scarlet fever. It is satisfactory to learn no deaths have resulted. One mild case of typhoid also cropped up, but happily it did not spread. The entire absence of means of isolation, the only protection in such cases, is a most regrettable fact and must have seriously handicapped the officials in contending with the disease. The committee have had under their consideration many times, the necessity of providing an isolation hospital, but notwithstanding, this most important matter has always been put aside, other pressing questions receiving attention. The folly of delay has surely now been clearly brought

home to them and we hope that definite steps will be immediately, if not already taken, to provide a separate hospital, without which an asylum cannot be considered complete.

ASYLUM REPORTS (continued).

FIFE AND KINROSS DISTRICT.

This is a very full report, and there are evidences of able and enthusiastic management. The admissions numbered 122—11 per cent. less than last year—and of these 39.3 per cent. recovered. Six female private patients were in residence, but no males of this class are received. In twenty cases the cause of insanity was assigned to intemperance in alcohol. The death-rate was 7.8 per cent. on the average number resident. Death in ten instances was due to forms of tuberculous disease. Unfortunately, one suicide occurred, but accidents will happen despite the amount of care exercised. The farm account shows the satisfactory surplus of £528. The average rate of board during the year was £27, and the cost of maintenance £26 8s. 9d. There is a call for extension of the accommodation, and the Board are wisely considering the question. The arrangement of supplying the necessary butcher meat direct from the farm has been found quite practicable, while the supply, on the whole, is better. A man who had been in the asylum for many years, and who had not been visited by strangers or apparently exposed in any way to infection, developed measles. The occurrence of a solitary case of measles is certainly a strange and interesting episode. Dr. Turnbull says the system of providing houses for members of the staff is of great advantage in promoting its stability, and in retaining the services of experienced and trustworthy attendants. Verily these are sage remarks, exactly expressing our sentiments, and we have often advocated the adoption of that system. An interesting and novel feature in this report is a table illustrating the weight on admission and discharge, form of insanity, age, and length of residence of those recovered. The Commissioners' reports are very satisfactory. The doors on the female side, with one exception, were all found to be unlocked, and on the male side the same freedom prevailed, with the exception of some parts of the main building.

ATB DISTRICT.

The number admitted during the year was 134, 105 discharged, and 53 died, leaving 219 males and 260 females in residence. Among the admissions was a girl suffering from typhoid fever. The recovery and death-rates were both high—53.3 and 10.9 per cent. respectively. The changes in the staff of attendants continue somewhat numerous. Dr. Skæe says, "It is difficult to obtain attendants but much more difficult to retain them. The trouble is with the under attendants; they come and go pretty much as they like." This is a very unsatisfactory and regrettable state of affairs, and counteractive methods should be adopted without delay, as the recovery and comfort of the patients are at stake, and new men ever appearing on the scene must be a great source of anxiety to all concerned. The conditions of the service should be improved as much as possible, and we can add our recommendations to that of the Commissioners, that if suitable cottages were erected to enable the men to marry and settle down, a trustworthy and efficient male staff would be secured. The out-door occupation of the patients requires more attention, only a very small percentage of the men being thus employed. The Commissioners who report that the asylum throughout was found in excellent order, rightly recommend the installation of electric light, which the Board should favourably consider, if they want to keep abreast of the times. There is, strange to say, no table showing the probable cause of insanity. Phthisis as a cause of death appears in eleven cases—20 per cent.

GOVAN DISTRICT.

The changes in the population have been excessive; 240 admissions, 207 discharges, and 75 deaths. The recovery rate is satisfactory, 44.5 per cent., but the death-rate, 16.6 per cent. on the average daily number

resident, is exceptionally high; in fact, it is the highest we have yet had to record. Of the causes of insanity, 19 per cent. are attributed to drink. We are pleased to note the employment of the patients receives careful attention. The Commissioners' reports are very satisfactory. At a recent meeting the Council resolved to take into consideration the question of providing an observation ward for the treatment of cases arising through the abuse of alcohol. It was explained that such a ward would save many from the stigma of having been committed to a lunatic asylum.

DUNDEE ROYAL.

Various legacies have been intimated to the Institution during the year. The working account shows a deficiency of £856. 125 patients have been admitted, 77 discharged, and 38 died. The advanced age of many of the patients admitted is remarkable, 12 being over 67 years. The proportion of recoveries is 34.4 per cent., while that of the deaths, calculated on the total number under treatment, is 7.1 per cent. The chief event of the year was the erection and completion of a new private asylum. The changes in the staff continue greater than are desirable. Drink was the probable cause of insanity in 32 cases. There are no Commissioners' reports appended. We would like to see this rectified in future.

MURRAY'S ROYAL (PERTH).

The statement of accounts shows a surplus of £334, and the farm account also shows a surplus of £198. The total number of cases under treatment was 171; 40 were admitted, 29 discharged, and 10 died. The recovery rate is rather low, 35 per cent. on the admissions and the percentage of deaths is 7.5. The changes in the nursing staff have been more numerous than usual, and the difficulty of obtaining suitable men has been greater than for many years past. Great attention appears to be devoted to the training of attendants, not only in the special work of the cure of the insane, but also in such important work as housekeeping and cookery. An endeavour is also made to provide as many as possible of the nurses with a course of training in a general hospital in addition to their asylum experience. It is quite apparent that Dr. Urquhart endeavours by every means to promote the recovery, happiness, and comfort of all the patients. A distinctive feature of this institution is that only private patients are admitted. Owing to the increase in the number resident, and pending the erection of two new villas, the admission of patients depends upon the vacancies occurring from time to time.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 9th, 1902.

THE NEW LAW ON PUBLIC HEALTH.

THE Senate has just passed without modification the Bill sent up from the Lower House on the regulation of general sanitary measures relating to the Public Health. The following are the principal provisions of the Bill which will soon become law:—

Art. 1. In every commune the Mayor is required, with a view of protecting the public health to determine the precautions to be taken to prevent or cause to cease transmissible diseases, especially the disinfection or destruction of objects used by the patients or of any object in general that might serve as a vehicle to contagion. To insure the salubrity of houses and their dependencies, especially as regards the service of water supply and sewage.

3. In case of urgency (epidemics or any other imminent danger to the public health) the prefect can order the immediate execution of the measures prescribed by Art. 1.

4. The list of diseases to which the dispositions of

the present law will apply will be drawn up, within the six months after the promulgation of the present law, by a decree of the President of the Republic, rendered conformably to the advice of the Académie de Médecine.

5. The notification to the public authorities of every case of disease mentioned in the above article is obligatory for every doctor or midwife who recognises its existence.

6. Vaccination is obligatory within the first year, and re-vaccination in the course of the eleventh and twenty-first year.

The parents or guardians are responsible for the execution of the above measure.

7. Disinfection is obligatory for every case of disease affected by Art. 4 and the method of disinfection must be approved by the Minister of the Interior, on the advice of the Public Sanitary Committee.

9. When during three consecutive years the number of deaths in a commune exceeds the average mortality of France, the Prefect is held to institute a special inquiry as to the sanitary conditions of the commune, and, if necessary, to appoint measures to remove as far as possible the cause of the excessive mortality, paying particular attention to the supply of good water.

12. When a house in towns of 20,000 or more inhabitants is found dangerous for the health of the occupants or the neighbours, the Mayor or the Prefect will invite the Local Sanitary Committee to give its opinion as to the necessity of forbidding the occupation of a part or of the whole of the house until the conditions of insalubrity have disappeared, and as to the nature of the work to arrive at that end.

14. If the occupants refuse to quit the house they will be liable to a fine, and the Court can order their expulsion at their own cost.

20. Each department will be divided up into sanitary districts, and each of these latter provided with a sanitary committee. The sanitary board of each department will be composed of from ten to fifteen members, comprising three doctors, one chemist, one engineer, one architect, and one veterinary surgeon.

30. Any person or persons who will put any obstacle to the accomplishing of the duties of the Mayor or of the Sanitary Commission will be liable to a fine of from £4 to £20.

34. The present law will not enter into effect until a year after its promulgation.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 8th, 1902.

THE RESULTS OF GASTRO-ENTEROSTOMY.

We are fairly well acquainted with the immediate results of this operation, but not so well with the later history of cases operated on.

Dr. O. Kaisen, of Breslau, has made an attempt to supply information on the point in an article in the *D. Zeit. f. Chir.*, 61/3 and 4.

Forty-four cases operated on by Kocher, of Bern, before the end of 1899 afford the material for the investigation. Of the cases operated on 15 were for non-malignant disease, and in the remaining 33 the disease was of a cancerous nature. In the first class of cases

anterior gastro-enterostomy was performed in 7 cases the posterior operation in 5, and in 3 the Roux (the Y method) operation was performed. In 10 cases the results were satisfactory, 3 patients complained later of trouble only indirectly connected with the stomach affection; and in two no improvement took place. Of these two a grave continuing anæmia led to a suspicion that the disease was malignant, the other suffered from chronic adhesive peritonitis that caused further disturbances.

In all the cases ending favourably, the parts were alleviated and the condition as to nutrition improved rapidly. The dilatation only rarely underwent any essential improvement, but independently of this, the functional power of the stomach increased.

Bile was frequently observed in the contents of the stomach after the operation, whatever method was employed. Decomposition of the contents however, was only observed twice. One case improved after washing out the stomach, and the other was one of adhesive peritonitis.

In the 33 cancerous cases, the anterior operation was performed 24 times and the posterior 19. Twelve, or 36.3 per cent. died from the operation. The remainder had an existence of from 1 to 12 months with an average duration of 3.6 month.

Decomposed stomach contents were observed 7 times after operation; 5 of these patients died of it; the remaining 2 improved after washing out.

The cause of the complication was probably regurgitation of material from the intestines into the stomach. The mode of operation had no influence on the occurrence or non-occurrence of this backward flow.

In four cases in which rapidity of operation was called for, Murphy's button was used. In three cases it passed away downwards, and in one it was the cause of perforative peritonitis.

On comparing the probable size and mobility of the tumour, as observed before operation, with the condition actually met with at the operation, it was remarkable how untrustworthy such conclusions drawn before operation were, and how frequently tumours were taken to be smaller and more movable than they really were.

Free hydrochloric acid was found in the stomach contents in cases of carcinoma; in two of these the malignant disease was situated on an old ulcer, and in one the disease was probably a primary carcinoma of the pancreas that had extended into the stomach.

At the Medical Society Hr. A. Baginsky held forth on

CHRONIC PERITONITIS

in which recovery had taken place. He reminded his hearers of the cases of probable tuberculous peritonitis that offered no prospect of recovery without operation, but which, as a matter of fact, really did recover later on without surgical interference. The diagnosis of tuberculous peritonitis was certain only after microscopical examination or after successful animal inoculation. In the three cases shown the diagnosis was as clear as clinical observation could make it.

The first case was that of a girl admitted in November, 1900, with a history of a four months' illness and loss of appetite. There were abdominal pains, and the abdomen had steadily increased in circumference. The child had a temperature up to 39°, pleuritic exudation and a good deal of fluid in the abdomen, and was very

ill. Under soft soap rubbing all the symptoms gradually disappeared, the condition improved, and in six weeks she was in a condition to be discharged, greatly improved. She was now well nourished, and there was nothing the matter with the abdomen.

In the second case the diagnosis of tuberculous peritonitis was better supported. In this a child with a temperature of 39° had an abdominal exudation. The soft-soap treatment had a great and visible effect. The fever receded, and the more the fluid was absorbed the plainer were nodules to be felt in the abdomen. These also gradually improved, and the abdomen was now quite clear and the child in good health.

The third case was that of a child suffering from typhoid fever, in the course of which the vomiting was remarkably severe. At the end of three weeks the fever subsided, but suddenly the temperature went up for a short time to 41° C. High fever now came on, and an exudation formed in the abdominal cavity. Here also under the soap inunction both exudation and fever subsided.

He would not go so far as to reject operation in tuberculous peritonitis, but he would certainly exhaust all the methods of internal treatment before operating. For him the most active method of treatment was a continued rubbing with soft or karrel soap (*Schmierseife*).

Hr. Cassel would operate in cases of great prostration after long-continued illness.

Hr. Lassar spoke favourably of the good results he had obtained with soft soap in the treatment of epididymitis with effusion into the surrounding parts. Equal parts of iodide of potassium and green soap were applied to the scrotum, and left on whilst a bath was taken, otherwise the scrotum could not bear it. In struma, not too pronounced, the mixture seemed to be of service.

Hr. Ewald observed that chronic peritonitis was sometimes recovered from whatever treatment employed.

Hr. Senator thought the most effective treatment was rubbing with soft soap. Latterly he had added iodoform vaseline or lard, as otherwise the skin would be irritated too much. The better feeding of a hospital was certainly not the factor that brought about spontaneous recovery, as children of the better classes recovered under the soft soap treatment, although as regarded their feeding nothing more could be wished for.

Hr. Baginsky rubbed in very little pure soft soap, but so thoroughly that it all disappeared, and there was no great irritation of the skin.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Feb. 8th, 1902.

GASTRO-ENTERO-ANASTOMOSIS RETROCOLICA.

At the Gesellschaft der Aerzte, Forok demonstrated a pathological preparation which showed how successfully a gastro-entero-anastomosis retrocolica can be performed, although in the present case the patient survived the operation only eighteen hours. The patient, a female, æt. 53, had suffered from pain in the gastric region for a year and a half, but it was not until January, 1901, that great pain with emaciation and vomiting set in, for which she was admitted to

hospital. She had had two children, and during the gravid state had osteomalacia on both occasions, and in consequence of this the chest was much deformed. In the pyloric region a large, hard, immovable swelling was present.

Laparotomy confirmed the diagnosis of pyloric cancer. The organ was bound round with adhesions which, with the deformity, increased the difficulty of the operation, which was performed after Kocher's method, with a few modifications, viz., the stitching of the bowel into the posterior part of the stomach in such a position that the bile should not pass towards the stomach beyond the orifice of the bowel. The preparation showed how successfully this can be done by simply making a fold in the stomach wall to act as a valve. The whole of the pyloric end of the stomach was carcinomatous.

INTRACRANIAL COMPLICATIONS IN MIDDLE EAR DISEASE.

Frey brought two patients before the Society in whom discharges from the ears had led to very serious complications. The first was a hair dresser, æt. 25, who had suffered from otorrhoea of the left ear from childhood, which became aggravated in February, 1901. A few weeks later the patient complained of headache, vertigo, vomiting, with stiff neck, and later delirium, and high fever followed. Pulse 84. Soon after this he became excited, laughing, speaking loud, and afterwards met with difficulty in finding a word to express himself.

It was decided to open up the middle ear on the left side, when it was found full of granulations and cholesteatomata. After trepanning the tegmen tympani, a patch of dark reddish dura, about the size of a shilling, was observed in the temporal fossa. An incision there was followed by prolapse of the temporal lobe, which seems to have been punctured. Along with it came a large quantity of foul-smelling pus. The prolapsed brain was removed and a tampon of iodoform gauze applied. On the fourth day after the operation the temperature was normal, but a further prolapse took place which was also removed. Fourteen days later the patient was still restless with aphasia and para-aphasic phenomena. In three weeks the disturbances were still more accentuated, the patient being quite unable to multiply numbers. Three months afterwards the wound was quite healed up, and the hearing restored to five metres. The patient appears now to be in fairly good health.

In the second case, a labourer, æt. 26, was suddenly attacked with severe symptoms of meningitis after trepanning of the mastoid—vertigo, vomiting, pain in the head, &c., but no fever. There was throbbing in the left side of the head, which was hyperæsthetic, as well as the whole left side of the body.

An operation was at once performed to relieve tension, but although the temporal lobe and cerebellum were punctured in seven or eight different places no abscess could be discovered. Shortly after this the symptoms were repeated, with right facial paralysis, stiffness of neck, and sensory aphasia. Again, the temporal lobe was punctured with a negative result. On the following day a large quantity of pus made its appearance from an extra-dural abscess, apparently in the temporal region. After this the patient made a perfect recovery.

Both cases point to the fact that clinical symptoms alone are not sufficient testimony of the

abscess or of its site. From these experiences also we find that repeated puncture of the brain does no harm to the cerebral structure. We also learn that otitic abscess of the brain can be easily dealt with through the middle ear.

Schiff thought otitic surgery would be better guided if surgeons could differentiate between a cerebral abscess pure and simple and purulent meningitis. Many cases were not interfered with owing to the presence of meningitis, which was inoperable, while purulent otitis is at once benefited. Puncture in the lumbar region is another method of diagnosing whether it is purulent or lymphoid. A clear fluid without coagula in the puncture opening is against the diagnosis of meningitis and in favour of the existence of abscess.

Hammerschloy thought that otitis with purulent meningitis was absolutely incurable, although a few cases certainly had been drained of the purulent matter and cured. But as a rule it was difficult with their present knowledge to discriminate between these cases, and it was almost criminal to lay meningitis open in mistake for an abscess. In reference to lumbar puncture as a means of differential diagnosis he thought the time for operating was long past before the diagnosis could be determined.

Schiff dissented from the view that the possible existence of meningitis counter-indicated operation for abscess. Many cases of meningitis did very well after operation.

Redlich referred to various other complications in the brain which might lead to a wrong diagnosis, such as meningitis serosa, curable encephalitis, or tuberculous meningitis. There was no doubt that lumbar puncture was an excellent means of diagnosis when purulent exudation was present; still there was a certain amount of danger even with this operation, as a tumour of the brain has been known to cause sudden death after lumbar puncture. The absence of fever or a sub-normal temperature is the evidence of an abscess, as meningitis and encephalitis are usually associated with rise of temperature.

Brewer thought that tuberculous meningitis with otitis was not uncommon but misleading. He has seen both sides of the head operated on, and in both with negative results. The lumbar puncture was the best diagnostic agent.

The Operating Theatres.

ST. PETER'S HOSPITAL.

CASE OF NEPHRO-LITHOTOMY, ILLUSTRATING SOME OF THE DIFFICULTIES OF THE OPERATION.—Mr. SWINFORD EDWARDS operated on a young man, æt. about 20, who had suffered with pain in the right renal region for the past three or four years. There were no marked symptoms in the urine, although it was said to have been blood-stained on one occasion. An X-ray photograph showed nothing. A cystoscopy revealed a right ureteral orifice, which was somewhat prominent and gaping. As the renal colic from which the patient suffered was rendering him quite unfit for work, and as the appearance of the right ureter rather favoured the suspicion of renal calculus, Mr. Edwards determined to explore through the usual lumbar incision. The muscles in the flank having been divided, what was taken to be the false capsule of the kidney was incised, but it was found that

this was really the peritoneum which was, of course, at once closed by suture. Mr. Edwards now dissected farther back, in order to get at the kidney, but was again unfortunate in opening the peritoneum and that portion of it which lies immediately over the liver; this last, indeed, was momentarily mistaken for the kidney. This second rent was again accurately adjusted, and Mr. Edwards endeavoured to ascertain the position of the kidney by careful bimanual manipulation, when it was found that the kidney was lying in the right iliac fossa; in other words, as he remarked, the patient was suffering with marked ptosis of that organ. The false capsule of the kidney was now successfully opened, and the organ, having been freed from its capsule, was carefully palpated. Mr. Edwards failed, however, to feel a stone until after several attempts; he then discovered two flattish and small stones which lay in the pelvis under cover of the renal substance. These stones were removed through the posterior aspect of the pelvis, and the kidney, which had been pulled up into the wound for this manoeuvre, was allowed to fall back. A couple of large drainage tubes were passed down into the opening in the pelvis, and the wound was about to be closed in the ordinary manner when it was noticed that more bleeding was going on than usual, therefore, Mr. Edwards passed his hand again into the wound and partially again delivered the kidney, he then carefully examined the neighbourhood of the pelvic wound, two small capsular vessels were found bleeding; these were ligatured. In doing this the electric forehead lamp was found of great service, as the kidney could not be entirely delivered out of the wound. Mr. Edwards thought what he had done for the arrest of the hæmorrhage was sounder surgery than trusting to gauze plugging. He said the first difficulties encountered in the operation were due to the abnormal position of the kidney which, perhaps, many might have supposed could have been discovered by a careful examination before the operation, but the right side of the patient's abdomen was so tender that he held the part perfectly rigid, thereby precluding accurate diagnosis; this fact was overlooked when the patient was under the influence of the anæsthetic and before commencing the operation. The next point was when once the kidney had been exposed to distinguish the presence of the calculi. Had palpation failed, he said, he was about to incise the kidney through its external border, and through the incision pass his finger into the pelvis. The other point was the bleeding that followed the incision into the capsule, especially if it be borne in mind that the pelvis was opened by the finger nail scratching process, hæmorrhage being usual when the finger-nail only is used; he thought when this happened the best plan is to bring the injured part as near the surface as possible, and pick up any bleeding points.

A week after operation the patient was progressing favourably.

Killed on the Railway.

A few days since Dr. Weir, the Medical Officer appointed *pro tem.* by the Tottenham District Council, was found on the line of the District Railway in London with his legs broken and other injuries about the head and body. The discovery was made through a railway carriage door being found open on its arrival at a station. He was at once conveyed to Guy's Hospital, where he succumbed to his injuries next day.

WEDNESDAY, FEBRUARY 12, 1902.

SCHOOL BOARDS AND VACCINATION.

THE London School Board is, on the whole, an excellent, if somewhat extravagant, body. Since the time of its creation it has gathered a good deal of the wisdom that is learnt from experience, and has shown a considerable amount of adaptability to the fresh responsibilities that have been thrust upon its shoulders by the force of public opinion. For many years past we have continually urged in the columns of THE MEDICAL PRESS AND CIRCULAR the need of efficient medical control of the juvenile population entrusted to the care of the Board. The scholars are congregated together in the various schools at an age at which they are peculiarly prone both to convey and to acquire communicable diseases. There can be no reasonable doubt, to quote an instance in point, that the great wave of diphtheria that of recent years has swept over, not only the Metropolis, but also the length and breadth of the United Kingdom, has been due in a great measure to the development of the Board School system. Indeed, the situation with regard to the spread of infection has been formally recognised in the appointment by the London Board of a medical officer whose chief recommendation is a practical acquaintance with school diseases. The movement thus inaugurated is still in its infancy, but it is to be hoped that ere long the Board School population of London will be under systematic medical control. At the present juncture, when London is in the grip of a raging epidemic of small-pox, the question of the medical control of the schools becomes a matter of vital importance to the community. Moreover, when we consider the enormous daily stream of travellers to and from every part of the United Kingdom, there seems to be no remote improbability that the invasion of the Metropolis to-day may to-morrow be that of any other town or hamlet in the British Islands. The attitude of the London School Board with

regard to vaccination, therefore, has a peculiar interest that may fairly be regarded as national. From that point of view last week's proceedings at a meeting of that body are not altogether reassuring. A prominent member, who proposed in future to admit only vaccinated children, was ruled out of order, presumably on the ground that such a step would be *ultra vires*. He then substituted a motion to present a petition to the Government for an alteration of the law, so as to allow School Boards to admit only vaccinated children. In supporting that proposition he very properly pointed out that every other public body was doing something to combat the outbreak of small-pox. He urged the Board also to help in the matter, as it was concerned with the health as well as the education of those who attended the schools. His seconder aptly remarked that unvaccinated children were excluded from the foundation schools belonging to the City of London. On the other side, it was contended that the question of vaccination was one for the sanitary authorities and not for the School Board. Further, that the schools had been remarkably free, and that by far the greater number of cases had occurred among adults. One reverend gentleman said that to turn away children who had not been vaccinated from their schools would be the cruellest possible thing. In our opinion there would, however, be a worse one—namely, to allow small-pox to enter a crowded school with an absolute certainty that, let us say, something like two-thirds of the unvaccinated children who took the disease would die. The result of the discussion was that the motion was thrown out by a large majority. The inevitable conclusion is that one of our greatest London public bodies is under the sway of anti-vaccinationist principles. Unfortunate as such a situation would be at any time, under present circumstances it becomes fraught with dangers of the gravest kind. So far as it is possible to judge, the epidemic has simply shown enough of its power to warn us of the tempest that is yet to come. Does the London School Board propose to sit apart under the unsatisfying plea of *non possumus*? Should small-pox invade the schools, the public will certainly demand some more solid justification of their conduct from the body whom they have elected to administer the Board School system in its entirety, both from the educational and the sanitary points of view. If the Board refuse to take efficient action it is possible that higher authorities will have to take the matter in hand. It will be curious to note the action of the Government should the London outbreak assume panic proportions. Mr. Balfour's retrograde Vaccination Acts have created the "conscientious objector," and have set back the hands of the clock, in defiance of the deliberately expressed convictions of the medical profession. If anything could justify London and provincial School Boards in disclaiming any responsibility in the exclusion of unvaccinated

children from their schools, it would be the views of Mr. Balfour's Government as duly recorded in the statute law of the land. The far-reaching nature of the disastrous principle adopted therein may be traced in last week's sitting of the London School Board. Were not the results heavy with disaster and death it would be a matter of simple philosophic interest to note how hard Nemesis has followed on the heels of the statesmanship that has pandered to the follies of a noisy and mentally ill-balanced knot of faddists.

THE OBSTETRICAL SOCIETY OF LONDON.

In these early days of the new century the Obstetrical Society of London has felt its pulse, and has discovered such qualities of vigour and elasticity as betoken an entire absence of arterial or cardiac senility, and demonstrate that in spite of its years it retains the fire and energy of youth. How far this is the result of the transfusion of new blood into the Council and how much is due to an originally robust constitution, it were difficult to determine, nor is such diagnostic precision necessary. We are concerned with symptomatology rather than with etiology, and may therefore say at once that the clinical condition of this Society, as indicated by its action at the annual meeting on the 5th inst. is exceedingly satisfactory to its friends. As will be seen from the report of that meeting which we publish in another column, two important alterations in the laws were suggested by the Council and adopted by the Society. The first has reference to the recognition of the eligibility of medical women to the Fellowship of the Society. When the Society was founded, the law, as the President in his Annual Address pointed out, stated that "all medical practitioners possessing a qualification registrable in the United Kingdom shall be eligible for election as ordinary Fellows of the Society." This was before the invasion of the mysteries of the Temple of *Æsculapius* by womankind. When one woman after another surmounted the barriers of prejudice and exclusiveness that closed that Temple's portals, the Fathers of the Society felt that their own particular shrine must, at all events, be safeguarded, although an outside observer would doubtless have thought that it was of all shrines the one to which women might most fairly crave access. So the opening words of the law which we have just quoted were altered, so as to read "All medical *men*," &c., the alteration being italicised to emphasise the sex restriction. Under the influence of a broader and more catholic spirit, the word "*men*" has now been changed back to "practitioners"; and consequently there is now no official obstacle to applications by medical women for admission to the Fellowship of the Society. We, of course, realise that they may still fail to pass the ordeal of the ballot; but we trust that when the first application is made the suitability of the candidate will be judged by precisely the same standards as determine the election of men, and that not a single black-ball will be the result of the sex element. In the meantime we cor-

dially congratulate the Obstetrical Society of London on its advance along the path—we will not say of chivalry, for we do not so regard it, but of fair play and emancipation from prejudice. The day is long past when the question whether women ought to become members of the medical profession can be considered as other than a mere academic discussion; they *are* members of the profession, and not a few of them have so justified their admission that the medical profession would be poorer for their absence. All that they have asked is a fair field and no favour; and this we must grant them under the penalty of being branded as a jealous, intolerant and small-minded profession. The second alteration proposed by the Council of the Society and adopted by its members is one of far less momentous import, but it is an additional mark of progress. It is now decreed that "authors of papers accepted for reading before the Society are at liberty to publish them in any scientific periodical after they have been read, provided that acknowledgment of the fact of their having been read before the Society is made in such periodical." Clearly this innovation cannot be productive of other than good. Many valuable papers are read before this Society which fail to receive the notice they deserve as long as they are published only in the Society's "*Transactions*," because these are necessarily accessible to comparatively few, whilst in the weekly and other medical journals authors can address a much wider circle of readers. On the other hand, the publication of such papers in the general medical press is not in the least likely to interfere with the Society's "*Transactions*." There will thus be a treble gain: to the medical public, because it will be made acquainted with good work otherwise hidden from it; to authors of papers, who will meet with a greater share of the recognition to which good work is entitled; and to the Society itself, because authors will be more encouraged to bring their work before the Society when they feel that they are at the same time addressing a much larger audience through the medium of the Press. In this, as well as in the opening of its doors to medical women, the Obstetrical Society of London is to be congratulated on its progressive spirit.

TEA INTOXICATION.

TEA has for good or evil become the food auxiliary of the Empire. On its introduction into England there were no end of disputes on its good and bad qualities, and the discussion was carried on with all the bitterness of a theological dispute. At length the leaf won its way, ousting all rivals, and discussion came to an end when Johnson confessed that he was "a hardened and shameless tea-drinker, who has for many years diluted his meals with only the infusion of this fascinating plant; whose kettle has scarcely time to cool; who with tea amuses the evenings, with tea solaces the midnights, and with tea welcomes the mornings." But it was not always so with the lexi-

cographer; in his boyhood days he knew not the taste of the "fascinating plant," and when his reputation was made other beverages washed down his meals. As a food auxiliary tea finds favour with Munson, whose opinion is certainly entitled to careful consideration as our greatest authority on dietetics. He cites the case of Arctic explorers, hunters, and trappers in the Canadian North-West, and of the troops under Lord Wolseley in the Ashantee Campaign during their celebrated march on Kumasi. It is, of course, well known that tea forms the beverage of Russian travellers in Siberia. But these cases do not answer the question, Does the habitual use of good black tea injure the health of the ordinary citizen? We think the question may be answered in the negative. But if asked of the children of the citizen and the workers that by continuous industry either of head or hands just manage to live, we fear that the answer must be in the affirmative. For children commencing school life to begin the day with a powerful cerebral stimulant, one that begets a habit, is wrong. It unduly stimulates the boy's brain, is not unfrequently the cause of sleeplessness, and gives a disinclination for wholesome food. The more studious the child the greater the mischief it works, and in one case at least we have known it to be followed by fatal results, and in many cases by incurable dyspepsia. For the poor who by unceasing toil just manage to avoid being submerged the make-shift dinner of tea and bread day after day is but a prolonging of the agony of a brave soul in a worn-out body, whose every nerve thrills with pain of insufficient nourishment. Of such a character was the patient Dr. Gordon exhibited before the Neurological Society of Philadelphia, who exhibited the symptoms of combined sclerosis and symptoms of functional disturbance. The frequent and imperative micturition and constipation which are so usual in tea intoxication were well marked. From time to time she had fainting fits and some fits that might be described as epileptoid, still the cerebral symptoms were not as well marked as in many of the cases on record, to wit: that of Dr. Slayter, whose sleeplessness, nervousness, and repeated twistings of the muscles of the face and extremities were followed by violent delirium, a pulse of 110, a very dry tongue, suffused eyes, no marked rise of temperature, tremulous hands and arms, and all the marked symptoms of delirium tremens. The evil of using tea as a substitute for food is, we believe, best combated by providing cheap dinners where it may be possible for the poor to secure nitrogenous food, wholesome in quality and sufficient in quantity to satisfy an ordinary man, and thus give him, once a day at least, a nutritious meal, and thus escape the horrors of tea intoxication with all its attendant suffering.

MR. ROBERT ARTHUR YOUNG, M.D., B.Sc.Lond., M.B.C.P.Lond., has been appointed Assistant Physician to the Middlesex Hospital.

Notes on Current Topics.

The Pith of Army Reform.

PROFESSOR CLIFFORD ALLBUTT, in the *Times* of February 3rd, has made a most valuable contribution to the subject of army medical reform. As medical officers are precluded from public controversy, he has adopted the sensible step of publishing the essential substance of a private letter sent to him by an army medical officer of ability and experience. The writer says that an increase of pay is not vital to the question, and that men of his rank do not lie under any social disadvantage. He altogether condemns the proposed examination ladder, on the ground that the tutelage of youth should in later life be replaced by personal character and initiative. He points out the futile waste of energy involved in keeping case books that are never read, and that are not filled up because of their scientific value, but because a patient receives a pint of milk or other extra. His suggested case-book for the medical officer would include cases of interest, surgical operations done, professional experiences, sanitary and bacteriological experiences, epidemics, campaigns, medico-legal matters, and the needs of field, barrack, and hospital organisation generally. In a word, he would make the individual officer think for himself instead of eternally agreeing with his seniors "For fourteen years," writes this candid critic, "I never met a senior officer worthy of the rank of P.M.O.; they were all men of the same stamp, men of no backbone; men who never supported their own officers; men who thought all they had to do was to agree with the G.O.C. and get some decoration; men who would say without a blush, 'I know you are right, but the general won't approve, so you must do so and so.' All this comes with a refreshing vigour from the heart of the disorganised camp. It is exactly the sort of evidence that should be laid before a Court of Inquiry, and is precisely the kind that it is impossible to get. The smooth tales of officers high up in the service are mere sprinklings of rose-water. Nor are the recommendations for fresh schools, fresh examiners, and fresh inspectors to be regarded as absolutely without bias, inasmuch as the commissioners of inquiry themselves would be among the first to share in the scramble.

Small-pox in London.

THE outbreak of small-pox in London is steadily increasing, a stereotyped remark that we fear will have to be made every succeeding week for several months to come. At the present ratio of increase the time may be near at hand when the question of adequate hospital accommodation will force itself upon the public and the Asylums Board with very disagreeable urgency. As yet there are no obvious signs of panic, although it is amusing to notice the change of front in various newspapers that have hitherto always showed a strong anti-vaccinationist leaning. On Monday, February 3rd, there were 75 fresh cases notified; on the 4th, 32; on the 5th, 37;

on the 6th, 27; on the 7th, 26; on the 8th, 32; and on the 10th, 45. At midnight on Saturday last there were 1,101 cases under treatment at the various Asylums Board hospitals. The Asylums Committee during the week have taken the important step of forbidding visits to patients at the London asylums, except in urgent cases of sickness. A similar precaution has been taken by many other public and private medical institutions. Its necessity has been shown by the outbreak in the Mile End Poor-law Infirmary, whence over sixty-seven patients have been removed suffering from small-pox. That number includes seven nurses, and in view of the pronounced anti-vaccinationist view of the Mile End Guardians it will be of interest to learn what steps, if any, had been taken to ensure that the nursing and administrative staff were protected against the disease by vaccination and re-vaccination. For unvaccinated officials to administer a public hospital of to-day would be nothing short of a scandal, and every death occurring under such a state of affairs would be little short of criminal. The Mile End Guardians, it may be noted, are organising public vaccination stations and voting sums of money for purposes of vaccination in a panic-stricken haste that is ludicrous in view of their former unbelief. At Lloyd's, the underwriters are freely insuring against the risks of contracting the disease. All classes of patients are said to be insuring themselves from £100 up to £7,000, but the average sum is £500, for which a premium of 2s. 6d. for vaccinated and 3s. 4d. for unvaccinated persons is charged. In badly-infected areas the rate is higher, and no medical certificate is required unless in the case of a claim. It has been officially stated on behalf of the Local Government Board in the House of Commons that the total number of cases in the present metropolitan outbreak was 2,656 up to January 25th. There is no prospect that the Government will introduce a Re-vaccination Bill during the present Session. Such a step would indeed be reaction itself coming from the parents of the "conscientious objector."

Prosecution for Non-notification of Small-pox.

THE charge brought against a London medical man for breach of the Notification Act, a case to which we alluded in our last issue, has ended in the dismissal of the summons. The facts are of interest to all who are likely to be brought into contact with small-pox—and who is not so liable when the Metropolis of the United Kingdom is in the grip of a great and rapidly increasing epidemic? From the evidence tendered in the police-court it appeared that when the defendant first visited the patient the latter was suffering from an erythematous rash upon the body, and the definite diagnosis was formed for the time being. Next day the rash had become general, and its character had altered so that the medical attendant formed the opinion that the disease was purpura hæmorrhagica. A second medical opinion was suggested, but declined on the

score of expense. The patient afterwards died and a girl with whom the medical attendant was acquainted shortly afterwards developed small-pox. Dr. Washbourne, who speaks as an expert in these matters, deposed that he had no doubt deceased suffered from the hæmorrhagic form of small-pox, which it was exceedingly difficult to distinguish from purpura hæmorrhagica. The summons was then dismissed. This case should be a warning to all medical practitioners to make themselves thoroughly acquainted with the known facts of small-pox and be on the look-out for typical and rare forms. There must always be a margin of error in human affairs, but the sum total of mistaken diagnosis that has come to light in the course of the present outbreak appears to have exceeded somewhat reasonable dimensions. It is far safer to err on the right side, and regard every doubtful case as small-pox, until proved to be otherwise.

Euthanasia.

THE current number of the *Spectator* contains an interesting correspondence on this subject. It is said the late Mr. Alfred Nobel offered to create at his own expense at Milan and Rome establishments where anybody who desired it could be painlessly suffocated by a gas he had found suitable. Sharp distinction must be made between suicide and natural euthanasia. For the latter the hygienist and medical man labour. A lust of death is morbid, and any encouragement must be stoutly resisted. Medical men recognise that for the public as well as for the profession there is only one sound principle—life must be held to be absolutely sacred, except when it has to be relinquished as a penalty for crime. Efforts to relieve suffering and render death painless are legitimate, but if euthanasia is to be achieved by means of a suicide club society and science must have none of it.

A Lunacy Maintenance Trial.

LAST week Mr. Justice Bigham and a special jury decided an action brought by Dr. Murchison, the well-known proprietor of Wyke House Asylum, London, to recover fees due to him for maintenance by a lady who had been under medical care in his establishment. The defendant denied that she was lawfully detained there, and counterclaimed for false imprisonment. From evidence tendered there could not be the shadow of a doubt that the unfortunate lady in question suffered from acute mania and a host of delusions during her stay at Wyke House. It is therefore difficult to believe that under such circumstances any person of experience in law matters could not have foreseen the inevitable result of resisting a claim for maintenance such as that brought by the plaintiff. In other words, the unfortunate defendant has been badly advised in attempting to establish a counterclaim for false imprisonment. It is likely that every lunatic under restraint since the world began has declared himself unjustly detained—that is to say, supposing him equipped with sufficient coherence to make any intelligible statements

During the course of the trial many indirect charges were made against the good faith of the proprietors of private lunatic asylums, and it was insinuated that their patients were retained after recovery from mercenary views. On a calm survey of the Murchison trial, it seems fair to retort that the defence of an indefensible action has put large sums of money into the pockets of the legal profession at the expense of an unfortunate client whose mind is obviously not of a stable character.

Dr. Bynoe and the General Medical Council.

THE lines of Dr. Bynoe have indeed fallen in unpleasant places. As most of our readers probably know, he was convicted of forgery in 1892, and was sentenced at the Central Criminal Court to nine years' penal servitude, a term which he has served in full. His defence was an *alibi*, which was upset by the statements of a Bank of England clerk, who swore that on a certain day a batch of notes was presented by a customer in one bundle after luncheon. That statement has since been admitted by the witness in question to have been incorrect, and as a matter of fact the Bank now admits the notes to have been cashed between the hours of eleven and one and three and four. Either time is covered perfectly by Dr. Bynoe's *alibi*, which accounts absolutely for his whereabouts at the hours mentioned. Under these circumstances the jury who tried the case addressed a memorial to the Home Secretary with regard to this "miscarriage of justice." Dr. Bynoe was offered remission of the remainder of his sentence upon conditions which he thought fit to decline. His name was struck off the *Register* by the General Medical Council, and as the Bank of England declined to submit to the Council a statement of the original error on the part of the clerk, Dr. Bynoe has recently brought against the Bank an action which has been dismissed by the Court of Appeal on a purely technical ground. The General Medical Council might well waive any technical objections to the restoration of Dr. Bynoe's name to the *Register*. As an innocent and deeply injured man he is entitled to that amount of reparation from the governing body of the medical world. It would be well to set on foot a movement whereby members of the medical profession might express their sympathy with one of their brethren in the most terrible and undeserved calamity that has marred his lifetime.

The Army Medical Officer as Sanitarian.

Now that the breakdown of the Army medical system beneath the strain of active service has awakened the national vigilance, it is to be hoped that Parliament will permit no half measures of reform such as the Government proposals in the case of the army generally. First and foremost, it will be necessary to form a clear idea of the real position of the army medical officer. Some time ago THE MEDICAL PRESS AND CIRCULAR advanced the proposition that he was above all things a sanitarian, a view that has since become widely adopted. A further suggestion that it would be well to engage the services

of some experienced medical officer of health from this country has been carried out by the appointment of at least one such civilian official in connection with the concentration camps at the Cape. A correspondent of the *Spectator* writes combating the view that the real analogy of an army medical officer is with the medical officer of health. He asserts that the army doctor has nothing to do with sanitary law, and that food and water supply are managed by other departments. No stronger argument could be advanced as to the radical defects of a system that takes away from medical control the agencies that every year destroy a vast number of lives in the British Army. Take the deaths among the troops from a preventable disease like enteric fever in a single year, and it will be at once evident that the present system, whether administered by army surgeons or "by other departments," is a complete and lamentable failure. To control food and water and drainage from a sanitary point of view is to control enteric fever.

The Diagnostic Value of Umbilico-Mammillary Measurements.

MEASUREMENTS of the distances separating the umbilicus from the nipples show a remarkable degree of uniformity as between the two sides of the body, and in certain morbid conditions these measurements may prove of service in demonstrating the existence of visceral hypertrophy or effusion situated in the upper part of the abdomen or lower part of the chest. The measurement is increased on the left side, for instance, in splenomegaly and pericarditis with effusion. It is increased on the corresponding side in pleurisy with effusion and pneumothorax, and the difference between the two measurements is in direct proportion to the amount of the effusion. In chronic pleurisy of old standing, on the other hand, the retraction of the chest wall determines a diminution, and the same holds good in respect of pericarditis which has been followed by adhesions.

The Diminution of Alcoholism.

THE temperance question rightly viewed is essentially one of personal and public health. The widespread abuse of alcoholic drinks is little less than a national calamity. The necessity for immediate measures for the stay of the spread of alcoholism is recognised by all interested in the physical efficiency of our people. Medical men and hygienists generally will therefore support the Home Secretary's proposals, which, when carried into law, may be expected to assist in the arrest of intemperance. Mr. Ritchie proposes to make it possible that when a person is found drunk and incapable in the public streets, he or she may be apprehended and charged, and if in charge of a child under seven be liable to a penalty of forty shillings or a month's imprisonment. It is also very rightly proposed that habitual drunkenness shall be a legitimate ground for separation. Publicans are to be notified of habitual drunkards. Grocers and others having off-licenses are to be placed, as regards the granting of their

licenses, under the absolute control of the justices. All clubs are to be registered, and where frequent drunkenness occurs in connection with club premises it is to be within the power of the police or other person to make a representation to the Court of Summary Jurisdiction, and if the case be proved they may order the removal of the name of the offending club from the register, in which case, if the club continues to act as a club, it would be liable to penalties. All this is well from the medical and sanitary standpoint, and deserving of full support.

The Use of Strychnine.

SOME time after the trial of Palmer, the Rugeley poisoner, strychnine came into general use as a therapeutic agent. The masterful description of its action by the Attorney-General, Sir A. Cockburn, made the alkaloid known throughout the land. As a therapeutic agent it has grown in favour until it has become the most used of all the tonic remedies. It finds a place in a large number of proprietary medicines—pills and mixtures. Its great and valuable properties are abused, both by the medical profession and the public generally. We in no way desire to depreciate its value as a simple bitter, or as a respiratory and cardiac tonic; but we do wish to draw the attention of the members of the medical profession to its abuse. We think that its prolonged use is fraught with evil. It is an excellent whip to a flagging heart, to be used at a crisis, but its continued use is harmful. Hare drew attention years ago to the rapid running pulse and great nervous irritation that follows from its too prolonged use in fevers. We are of opinion that its use in the treatment of delirium tremens, for which it has been strongly recommended, is not unattended with danger, particularly so when the patient is a female. Alcoholics can take very large doses of the alkaloid, but unless it is given in toxic doses it seems to produce none of its physiological effects. In full doses it, in such cases, not unfrequently produces a veritable ataxia, without contractures, as in Don Gonzalez Alvarez's case, and it occasionally causes a distressing and painful trismus.

The Conscientious Objector!

At the meeting of the Liverpool City Council last week Mr. Muirhead moved that the Council petition the Government for a repeal of the Conscientious Objector Clause of the Vaccination Act. Although all members present were in favour of such a petition, the matter was referred to the Medical Officer of Health in order that he might search out the weak points of the Act. Well done Liverpool and Mr. Muirhead! Of all the silly and weak clauses ever introduced into a Bill by a weak Government, the Conscientious Objector Clause was surely the silliest and weakest. A man might just as well claim exemption from having his child educated because he had a conscientious objection to education, and if he made his claim good he would have run one-half the risk of injuring other people as the law allows him to do

in the matter of vaccination. The State's interest in the child is greater than that of the parents, and it ought to insist on every member being protected from disease. If a father is fool enough or stupid enough to have a conscientious objection, that is no reason why the State should be fool enough or stupid enough to encourage him in his folly or stupidity.

The Biological Method of Identifying Semen.

SOME time since we described a novel method of identifying the source of blood stains based upon the fact that the serum of animals which had received injections of the blood of another animal determined turbidity of the serum of that animal when added thereto *in vitro*, enabling the medico-legalist confidently to affirm the source of a particular blood-stain. It appears from some researches made by Dr. Farnum, of Chicago, that a similar reaction takes place when semen is experimented with instead of blood. He found, in fact, that the serum of animals injected with the semen or testicular juice of a particular animal gave rise to a precipitate when added to a filtrate of the latter, while without effect on the similar preparations of other animals. Thus the serum of rabbits which had been injected with the testicular emulsion of a dog rendered turbid the filtered semen or testicular juice of another dog, no such effect being produced on human semen or the testicular juice of the bull. The reaction is a very sensitive one, inasmuch as not only is it available in respect of old-standing seminal stains, but even with the filtrate of dried and macerated semen left for thirty-eight hours on filtering paper or textile fabrics. Seminal stains over a month old gave a well-marked reaction, so that the medico-legal value of the reaction promises to be considerable.

The Life History of the Echinococcus.

THE life history of this interesting but pathologically terrible parasite has been carefully studied, and has been very fully described. Hitherto, however, the transformation of the scolex into hydatid cysts has been regarded as a retrograde pathological transformation of the little heads, it being assumed that these new productions undergo destruction, or at any rate became sterile. It would appear from the researches of Dr. Devé, of Paris, that these new cysts may, in their turn, become fertile, so that the cystic transformation of the scolex merely represents one phase of a progressive evolution. It follows that the life history of the echinococcus comprises two distinct cycles. Apart from the classic cycle, which comprises the passage of the parasite through the bodies of two successive hosts, there is, so to speak, a smaller phase, to which Dr. Devé gives the name of the para-echinococcal cycle, which runs its course within the same host, and may be perpetuated almost indefinitely, presenting this peculiarity—that at the termination of each evolution the scolex cycle, the parasite, when circumstances are favourable, may revert to its normal evolutionary cycle.

Disruption of Victoria University.

STRONG efforts are being made to draw attention to the proposed disintegration of the great Federal University of the North. A circular has been issued showing that such a step will seriously affect both the cause of higher education and the interests of the present graduates, and will materially depreciate the value of the degrees for which they have given time and money. The abolition of a great and successful University is without precedent in English history. The interests of nearly 2,000 graduates demand careful consideration and due protection. Unfortunately, the University Court appears to have pledged itself to the policy of disruption. It now behoves graduates to offer concerted opposition. The substitution of a wide-based, well-established, honoured Federal University for three small single college Universities, with the accompanying disadvantages of competition, variation in standards, and restrictions arising from local prejudice, is little less than disastrous to University training in this country. Meetings of graduates have been held in Leeds and at Manchester to protest against the suggested change, and a committee has been formed to carry on a vigorous campaign in the interests of the University, both in and out of Convocation. The ambition of Liverpool, strengthened by its youthful enthusiasm and ignorance of the traditions of University life, is insisting on a University of its own, but it behoves the University authorities and the Privy Council to see that such a contention should not be allowed to dislocate and set back for many years University life in our great northern centres. In the interests of higher education the matter is deserving of the most serious consideration.

Instruction in Anæsthetics.

At the last quarterly *comitia* of the Royal College of Physicians of London an important resolution was agreed to bearing on the compulsory instruction of candidates in the administration of anæsthetics. It was decided that all candidates passing the second examination, or an examination at a university in lieu thereof, on and after May 1st next will be required, before entering for the final examination, to furnish a certificate of having received at a recognised medical school and hospital instruction in the administration of anæsthetics to the satisfaction of his teachers. This is an example which ought to be followed without delay by all examining bodies.

Kahler's Disease.

AMONG the very rare maladies which are but occasionally met with is that to which has been given the name of Kahler's Disease, and of which only sixteen cases have been reported. The last instance was recently published by Donetti, and the chief symptoms were emaciation, weakness, grave anæmic pains, softening, fracture of the bones, and deformities. Heteroalbumose was found in the urine, sometimes preceding, sometimes following the period of pain and deformity. Post-mortem the ribs, sternum, and vertebral bodies have been

found to be affected by a sarcoma-like new growth, which first destroys the marrow and then invades the bone tissue. Lesions of liver, kidneys, and spleen have also been found. It is believed that, the bone marrow being unable to continue its functions, a special substance, albumin, is formed, which causes a true toxæmia and circulates in the blood.

The Noisome Tube.

COMPLAINT is rife as to the foul condition of the air in the tube of the Central London Railway. Unfortunately there are very adequate grounds for such lamentation, chemical analysis having shown marked impurity of the atmosphere therein. Drowsiness, headache and even nausea are common consequences. The air involved is becoming positively toxic in its action and unless a way of renewing the air of these railway burrows is quickly found the health of travellers will be more or less seriously affected. Efficient ventilation must be insisted on. It will be well that provisions for such be insisted upon in respect of all future "tubes." Considering the immense number of persons making use of this cheap and speedy means of locomotion the subject is one of pressing hygienic importance. We trust that the directors will not hesitate to take steps at once to improve the atmospheric conditions of a line which is rightly popular and is an unquestionable boon to the citizens of the metropolis.

A Novel Treatment for Tuberculous Peritonitis.

TUBERCULOUS peritonitis is a somewhat obscure affection in that it does not follow any definite lines of evolution and sometimes subsides, either spontaneously or after merely opening the abdomen, under circumstances which leave its behaviour a mystery. It is precisely in diseases of this uncertain prognosis that the largest number of remedies and modes of treatment are credited with curative effects for reasons which are too manifest to require demonstration. Dr. Baginsky showed at a recent meeting of the Berlin Medical Society three girls who had recovered from tuberculous peritonitis under treatment, which consisted in daily frictions with soft soap. Under the influence of the massage the exudation underwent absorption, the temperature returned to normal, and the general health improved. Dr. Baginsky does not pretend that all cases of the disease are likely to prove amenable to this treatment, but in view of the results which he has obtained he suggests that no case should be surgically dealt with until a fair trial has been given to this or some similar mild form of treatment.

THE Hunterian Oration will be delivered by Dr. Arthur Davies, at the London Institution, Finsbury Circus, E.C., to-day, February 12th, at 8-30 p.m. The subject of the Oration will be "Organotherapy—Ancient and Modern." Members of the profession will be welcomed.

Fatal Circumcision.

THE occasional death of infants from hæmorrhage after the ritual operation of circumcision performed by Jewish ministers is a circumstance which can be approached without touching on any religious question, and it is assuredly a catastrophe which calls for something more than mild remonstrance by the coroner. At an inquest held at the London Hospital last week on an infant who had succumbed to hæmorrhage of this kind it was given in evidence that the "Mohel," as the official is called, disadvised medical assistance being called in, with the result that, in spite of tardily-summoned aid, the infant died. Of course it may be, although nothing in the evidence suggested it, that the child was a "bleeder," in which event the unfortunate operator would be entitled to pity in lieu of blame. What the public have a right to require, whatever may be the cause of the hæmorrhage, is that there shall have been no delay in obtaining skilled assistance.

The Appointment of Extern Examiners in the Royal University of Ireland.

WE learn that the appointment of extern examiners in the Royal University of Ireland has been postponed. The cause of the postponement is generally believed to be the result of some informality at the last election of the Senate, whereby five of the former members of the Senate temporarily ceased to be members in consequence of not having been re-elected at the proper time. On this account the appointment of extern examiners has been postponed until the full Senate is elected. It will be remembered that the proposed appointment of these examiners had already given rise to some comment in the medical journals, owing to the fact that a difference of opinion prevailed amongst the members of the Senate as to what exactly was meant by an extern examiner. The definition of this term finally decided upon by the Senate was a gentleman who was not connected in any official capacity with the Queen's Colleges or with the Catholic University School of Medicine. The alternative definition was, we understand, one which would have the effect of excluding Irishmen from these appointments.

A Coroner on Unauthorised Post-mortem Examinations.

THE dicta of Mr. Wynne Baxter, the East London Coroner, at an inquest held at Stepney last week raises the question of the right of medical men to make post-mortem examinations in doubtful cases. In this instance a man who had been discharged from the National Hospital for the Paralysed and Epileptic five months previously with spinal sclerosis, died without having been subsequently seen by a medical man. The doctor who was called in at the last moment naturally refused a certificate of death, whereupon the relatives applied to the hospital medical officer, who, having made a post-mortem examination, certified to the cause of death. To this course the coroner took strong exception,

observing that such proceedings were "as irregular as they could be." To this view we respectfully demur. The man was known to be suffering from an incurable disease, and all that was necessary was to make sure that death was due to this and not to any intercurrent cause. By clearing up this point the certifying practitioner virtually dispensed the coroner from the trouble and expense of holding an inquest, but for reasons best known to himself the latter decided to hold his inquiry all the same, with the result of obtaining a verdict of "death from natural causes," though the jury requested him to call the attention of the hospital authorities to the circumstances. We maintain that, with the consent of the relatives, a medical man has a perfect right to make a post-mortem examination provided, of course, that there is no reason to suspect the operation of other than natural causes.

The Arrest of "American Specialists."

WE learn from a local paper that, on Thursday last, the Galway police arrested three persons, George Lilian, Madame Emily Lilian, and Mabel Lilian, who have been posing in the western capital of Ireland as the "Great American Specialists." They advertised themselves as "The Lilian American Herbal Company," and Madame Lilian, "the American lady specialist, treated diseases in the American system by the use of herbs, barks, and saps of trees." They are reported to have done a good business, but unfortunately this has now been interfered with by the unkind action of the police. The "specialists" await trial at Ennis, at which place the warrant for their arrest was issued.

The Disabilities of Colonial Practitioners.

A BILL has been introduced into Parliament having for object to place medical practitioners who have obtained their licence to practise at one or other of the Colonial schools of medicine on the same footing as their British *confreres*, so far as concerns their admissibility to the naval, military, and civil Services of the Crown. The Bill is hardly likely to make much progress, *inter alia* because it is open to the Colonial medical schools to obtain recognition of their degrees and licences in this country under the provisions of the *Medical Act* (1886) on conforming with the conditions therein specified.

The Vacant Physicianship at Sir P. Dun's Hospital.

IN consequence of Professor W. H. Thompson, the newly appointed King's Professor in the School of Physic in Dublin University, declining to take up the associated clinical duties at Sir P. Dun's Hospital, a locum tenens will be appointed for him by the Royal College of Physicians at the next monthly meeting on March 7th. As Professor Thompson at no time intended to take up these clinical duties, the appointment of a locum tenens has been expected. The names of several probable candidates have been mentioned, notably that of Dr.

H. C. Drury, who has been Assistant Physician to the hospital for a considerable number of years.

Death of Mr. Martindale.

THE death is announced of that eminent pharmacist, Mr. Martindale, of London, whose name is a household word with the medical profession as the author of that invaluable publication, the "Extra Pharmacopoeia." More than thirty years ago he held the post of Pharmacist and Lecturer in *Materia Medica* to University College Hospital. He, however, relinquished this post to go into business, in which he achieved well-merited success. For many years he occupied a prominent position in connection with the Pharmaceutical Society, for which he was an examiner for ten years, and of which he ultimately became President. He rendered signal service to pharmacy, and his genial, unassuming manners made him a general favourite.

The Manchester Brass Band.

THE Editor of our versatile contemporary, *The Practitioner*, with ruthless hand, has drawn aside the veil which has to some extent fortunately hidden from public view the acrimonious discussions regarding the arrangements for the forthcoming visit of the British Medical Association to Cottonopolis. The Manchester School of would-be medical reformers have constituted themselves into a "brass band," which fails to maintain harmonious concert with those gifted in the use of the bagpipes. The story is not edifying, but Mr. Malcolm Morris ventures to think it "points a wholesome moral." We hope that anti-midwife bores will cease from troubling, and that gynæcological patriots will be at rest under the apologetic sway of the Council of the Association, and that the discussion of medical matters in their scientific aspects at the annual picnic will not be endangered by the intrusion of the fads and fancies of well-meaning but fanatical "reformers."

Conan Doyle, Medical Practitioner and Patriot.

THE medical profession is not willing to forget that Dr. Conan Doyle is "a qualified practitioner," and the nation recognises and honours in him a specially qualified patriotism which cannot permit slander to pass unanswered. Dr. Doyle's able pamphlet, "The War in South Africa, its Cause and Conduct," has already been translated, or is in process of translation, into German, French, Danish, Swedish, Dutch, Italian, Spanish, Russian, Hungarian, Portuguese, and Welsh. We venture to think that Dr. Doyle's work will have a larger circulation than any medical monograph he "might have" written.

H.R.H. the Prince of Wales, F.R.S.

HIS MAJESTY THE KING has repeatedly evinced his deep interest and keen sympathy with medical research, and as F.R.C.P. and F.R.C.S. has made manifest his desire to support the highest traditions of the profession. It is particularly pleasing to find the Heir Apparent following in the footsteps of his

father, the King, and testifying to his interest in the advancement of science by becoming a Fellow of the Royal Society. The Prince of Wales, on his admission, declared: "I can assure you of my hearty sympathy with that scientific study and research which now, more than ever, has become so important and essential in our national life."

SOME people imagine that the most recondite problems in bacterial pathology can be cleared up by researches extending over two or three months. To all such be it known, on the authority of the President of the Local Government Board, that the Commission appointed to carry out researches in respect of Professor Koch's view of the non-communicability of bovine and human tuberculosis is not likely to report for a considerable time, in fact, not for two or three years at the earliest. If at the expiration of that period they are able to arrive at trustworthy conclusions the time will have been well employed.

THE attempt to call in question the powers of the General Medical Council did not meet with much success in Parliament last week, when Mr. Macnamara endeavoured to challenge the Council's recent decision in respect of Dr. Rendall, of Yarmouth. Mr. Jesse Collings declined to discuss the particular case, on the ground that it was still to some extent *sub judice*, adding that the Council's powers were clearly laid down in the *Medical Acts*.

THE Royal College of Physicians of Ireland has approved of the adoption in Ireland of Dr. Tatham's list of causes of death, which was drawn up for the Registrar-General for England.

PERSONAL.

DR. JOHN SHIVES has been called to the Bar at the Middle Temple.

DR. THEODORE SHENNAN has been appointed Pathologist to the Edinburgh Royal Infirmary.

PROFESSOR ERNST VON BERGMANN has had conferred upon him the title of Privy Councillor.

DR. LANCASTER, one of the oldest practitioners in Leicester, has recently died.

MR. H. T. WARING has been appointed Assistant-Surgeon to St. Bartholomew's Hospital.

DR. THOMAS G. RODDICK has been elected Dean of the Faculty of Medicine of McGill University, Montreal.

PROFESSOR VIRCHOW is reported to be slowly improving, but his strength is subject to much fluctuation.

DR. KELYNACK is giving a short course of lectures on "Tumours of the Kidney" at the Medical Graduates College and Polyclinic on Feb. 14th, 21st, and 28th, at 5.15 p.m.

DR. JAMES WHEATLEY, of Blackburn, has been appointed Medical Officer of Health for Shropshire, *vice* Dr. Porter, who resigned in order to take a similar post at Johannesburg.

DR. T. J. MACLAGAN is to take the chair at the Annual Dinner of the Edinburgh University Club, which will take place at the Criterion Restaurant, this (Wednesday) evening, at 7.15.

DR. ARTHUR LATHAM and Dr. Nachbar have prepared the English edition of Professor R. von Limbeck's work on "The Pathology of the Blood," which is to be issued shortly by the New Sydenham Society.

DR. W. T. EDWARDS was entertained by a large number of medical friends last week, to celebrate the jubilee of his connection with the Cardiff Infirmary. Dr. Edwards qualified as long ago as 1844.

MR. C. B. BALL, F.R.C.S., Regius Professor of Surgery in the University of Dublin, has been re-elected by the Council of the Royal College of Surgeons in Ireland as their representative on the General Medical Council for another term of one year.

HIS EXCELLENCY MONSIEUR PAUL CAMBON, the French Ambassador, supported by the Right Hon. Sir Joseph Dimsdale, M.P., Lord Mayor, and the Sheriffs of London, will preside at the thirty-fourth anniversary dinner of the French Hospital and Dispensary, on Saturday, April 26th, at the Hotel Cecil.

It is often uttered as a reproach that medical men hold aloof from local affairs and fail in their duty to the community. No such reproach could justly be hurled at Dr. Kingsbury, of Blackpool, for we note that he is a member of the town council, and sits on no less than thirteen committees, in fact; his omnipresence has on more than one occasion given umbrage to one or more of his fellow members.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

EDINBURGH TOWN COUNCIL AND THE USHER INSTITUTE OF PUBLIC HEALTH.

REPRESENTATIVES of the University recently met the Public Health Committee to confer regarding a proposal made by the former party as to the bacteriological work of the city being carried on in the new Usher Institute under the supervision of the Professor of Public Health, and in rooms specially set apart for the purpose. This work the University are willing and anxious to undertake for certain stated charges. The subject is to be further considered at a later meeting of the Public Health Committee, and meanwhile no decision has been come to. This question of the town's bacteriological work has been, so to speak, "in the air" for some time back, and the present state of matters is not entirely satisfactory. For many years the College of Physicians has been doing all sorts of reporting work gratuitously in the Laboratory for all medical practitioners, whether they reside in Edinburgh or not, and whether they are connected with the College or not. This reporting, begun in a very small way when the Laboratory was first instituted, and not limited to mere bacteriological examinations, but including as it does reports on tumours, &c., analysis of urines, examinations of blood and the like, has been more and more taken advantage of by the profession, and has grown to a dimension much beyond what was originally contemplated. It has doubly hampered the work of the laboratory by diverting funds intended to be utilised for the prosecution of research, and by unduly occupying the time of the laboratory assistants. With recent advantages in bacteriological diagnosis, especially the recognition of the diphtheria organism and the evident

typhoid reaction, the number of reports has increased to considerably over a thousand in the year, and it was accordingly felt that the time had come when the College might approach the Town with the view of getting some assistance in the carrying out of this work. Accordingly, about a year ago, it was arranged that specimens suspected of containing tubercle or diphtheria bacilli, and blood for the Widal test should be transmitted to the laboratory through the town, which was to pay the laboratory a small fee for each examination. At the same time all other reporting was to continue as before; and the same assistance as formerly was given to practitioners in the county who could not, of course, be recognised by the Public Health Authorities. This arrangement has worked to the satisfaction of all concerned. Extra assistance has been obtained in the Laboratory and a serious drain on the College funds has been lessened. The Town Council has now three courses open: it may continue as at present; it may transfer the work to the University; it may undertake it in a laboratory of its own in the new Fever Hospital. To many it must seem that the last course is the best, but until that hospital is opened it is scarcely practicable. There is, of course, no doubt that it would be a great advantage to the University to have the work done in its school of public health, both from an educational and a financial point of view, and it may reasonably be argued that a research laboratory has other and better objects than mere routine repertory work; but, be that as it may, it will be a little hard on the College of Physicians if, after having inaugurated and for so many years successfully carried on a work of great importance to the community at large, and in so doing having educated the practitioners of the town to use exact and scientific methods of diagnosis, another body steps in to reap the fruit which it has sown.

Literature.

MORRIS ON SURGICAL DISEASES OF THE KIDNEY AND URETER. (a)

It is difficult to write in too laudatory manner of the second volume of Mr. Henry Morris' latest work. If possible the interest excited by its perusal is even greater than that felt during the reading of the previous volume. This is probably largely due to the fact that the second volume is principally concerned with the surgery of the ureter. Mr. Morris points out that since the year 1894 about one hundred papers have been published on the subject of the surgery of the ureter, whereas in the five years previous to that date less than half-a-dozen had appeared.

Serious warning is given of the dangers attending a too devout worship of the methods of diagnosis by the use of the X-rays. "It is important that the surgery of the kidney should not be influenced by photography." The warning is at present just, but it is probable that radiography will advance in the future to a greater degree of accuracy, and will prove a much more trustworthy guide in renal diagnosis. The chapter on "Paraneuric or Perineuric Solid Tumours" is divided into two principal parts, the first is concerned with adrenal tumours, the second with tumours of the connective tissue type. No subject in his book do we think Mr. Morris has treated in a more masterly way. It is an extremely difficult one, both from a surgical and pathological point of view. These difficulties are thoroughly well recognised as such and discussed. The chapters on Renal Calculus are exhaustive, and contain a great many references to, and citations from, the works of others. Mr. Morris' own extensive experience in this branch of the subject is used in an admirable manner. The method adopted in considering the symptoms of renal calculus is excellent. "There are numerous morbid conditions other

(a) "Surgical Diseases of the Kidney and Ureter." By Henry Morris, M.A., M.B.Lond., F.R.C.S., Senior Surgeon to the Middlesex Hospital, &c. Vol. II. London, Paris, New York, and Melbourne: Cassell & Co., Limited. 1901.

than renal calculus which cause typical renal colic. Conversely, there are many cases in which the symptoms due to renal or ureteral calculus are not referred to the kidney or ureter at all, but to some other organ."

"Unsuspected calculi group themselves into three classes: (a) Calculi which cause no symptoms. (b) Calculi which cause symptoms that are not referred to the kidney or ureter. (c) Calculi which cause high temperature but indefinite (if any) renal or urinary symptoms." Could the difficulties of the subject be more forcibly illustrated?

Considerable stress is laid on the significance to be attached to unilateral rigidity of the abdominal muscles as indicative of the side on which the kidney is affected.

Mr. Morris has "never known pressure over a calculus kidney give rise to pain over the opposite kidney; and certainly not to pain only on the side not under examination, as Guyon and Albarran have observed."

Candid confession of mistakes the author has made, and the lessons to be learned from them adds greatly to the value of the book. Exploration of the kidney for stone by the needle is condemned.

It is not now considered necessary, or, indeed, advisable to avoid making incision directly into the expanded upper end of the ureter. It has been found that the operation wounds here heal readily if careful apposition of the edges be secured by sutures. No hesitation should be felt in making this incision in certain cases for the purpose of exploring the ureter with a sound. Abnormalities of development, injuries, and surgical diseases of the ureter are exhaustively dealt with. Almost every page contains reference to points of the highest practical importance. The manner in which these points, many of them still *sub judice*, are brought forward and discussed conveys a lesson in lucid exposition and close reasoning. In a review, necessarily brief compared to the importance of the book and its subject, it is impossible to give illustration of the characteristics of the work which place it on the highest level. The second part of volume II. contains twenty chapters, and about 400 pages dealing with the surgery of the ureter. Operating surgeons should not only have it on their shelves for reference, but should carefully read it—in connection with general abdominal surgery, gynecological operations, as well as renal surgery. Surprises are not unfrequently met with in the ureter; it is essential that the operator shall have well defined ideas carefully thought out beforehand, if he is to be in the best position to deal with such when they arise.

THE END OF AN EPOCH (a)

THIS is a very good example of what may be termed the imaginative scientific novel. A young bacteriologist is thrown into the society of a wicked German bacteriologist who has succeeded in cultivating a new kind of pathogenic organism, the *bacillus paradoxus*, a hybrid of the most deadly species of disease-producing germs. The wicked bacteriologist had just succeeded in preparing an immunising substance, the physiological effects whereof he had tried on his young and docile pupil, but had neglected to give or leave any details as to the method of preparation. At or about this date his stock of the *bacillus paradoxus* is accidentally scattered broadcast among a Derby Day crowd, and in the course of a few days the country is virtually depopulated by an epidemic of absolutely unprecedented virulence, only a few persons surviving to tell the tale, our author being one of them. The story is well worked out, considering the difficulty inherent to the popular treatment of such a topic and the adventures of our hero and author before, during and after the epoch-ending outbreak are described in a way which does credit to his imagination. Whether the public, profoundly ignorant of the elements of bacteriological science, will understand enough about it to follow the story is open to question, and if they do, we must be prepared for the development of a suspicion of, if not indeed, hostile feeling towards, adepts in a science so potentially destructive of the human race. Novelists

heretofore have not availed themselves to any extent of the marvellous possibilities which are presented by bacteriology, possibly, because they have feared to make themselves ridiculous, but we can look forward with confidence to the day when the generalisation of such knowledge, in the elements thereof, will enable authors to utilise the test tube and syringe, with effects as dramatic as those of the revolver and the poisoned bowl.

SIR H. THOMPSON ON MODERN CREMATION. (a)

THE fact that the volume before us is the fourth edition relieves the reviewer from the necessity of a detailed exposition or criticism of its contents. The greater portion has long been the common property of the scientific—we might have said of the intelligent—public. The earnestness of the now venerable author is well shown in the care with which he has prepared the present issue. We have, as in the last edition, six chapters and an appendix. In the three first chapters, which are historical, we have in the present volume statistics showing the progress of cremation in Europe and America to the end of the year 1900. The third chapter contains the details of a movement initiated by the Council of the Cremation Society in 1893 for the purpose of memorialising the Government on the imperfect method of death certification followed in this country. "The Council stated that it was defective in ascertaining even the fact of death; and untrustworthy in determining its cause, while many cases of death escaped certification altogether. The Home Secretary of the day, Mr. Asquith, convinced of the need of an inquiry, granted one by a Special Committee of the House of Commons, which fully admitted the allegations made, and recommended the remedies proposed by the society. Unhappily no action resulted, and this flagrant blot on the conduct of the social arrangements still exists.

The author still presents "the original argument," by which it is contended that cremation becomes in time a sanitary necessity in every closely populated locality. He here republishes, with some abbreviations, his earliest writings on the subject, "which appeared twenty-five years ago, as the facts then adduced and the conclusions drawn from them remain unchanged since that date."

PALMER ON MASSAGE. (b)

THESE lessons are written for students of massage, and are eminently practical. They contain such information in the letter-press and the illustrations as women require who purpose taking up the duties of a masseuse. Commencing with an historical sketch of her art, a sketch which, if necessary for a book of this nature, might be greatly improved in future editions, the authoress passes to consider the different systems and parts of the body, in the description of which she gives the elements of anatomy with sufficient fulness to make the subject intelligent to students, and in this part of the work the illustrations are both numerous and good. They illustrate the parts and the method of massage suitable for each, and cannot but be helpful to readers.

Massage of special regions is next considered, and the treatment of stiff joints, fractures, sciatica, varicose veins, and so forth, fully dealt with.

After these chapters follows a valuable one on the massage of children, and the work concludes with a good glossary and full index. We have pointed out the only defect in the book, the historical introduction, all else meets with our warm approval, and the authoress deserves the thanks of the profession for placing so very practical a text-book in the hands of student masseuses.

Obituary.

THOMAS WHITE, L.R.C.S.I., L.R.C.P.I.,
AND L.M.

We regret to announce the unexpected death of Mr. Thomas White, of Gardiner's Place, Dublin, who was a member of the staff of the Children's Hospital, Temple Street. Mr. White was formerly senior house surgeon of Jervis Street Hospital, and on the call for civil surgeons for the front volunteered for service. He was in South Africa for nearly two years, and distinguished himself by his devotion to duty. He was present at the death-bed of the late Sir William Stokes, by whom his undoubted abilities were appreciated. Later in the campaign he was stationed in Pretoria, and from that city he was sent under a white flag into General Delarey's camp to attend patients who had been suddenly taken ill, and for whom medical assistance had been requested from the British military authorities. He returned to Ireland at the end of last year, and was appointed to the staff of the Children's Hospital, Temple Street. Mr. White last attended to his duties on February 3rd. Later in the same day he was suddenly seized with illness, and died on the 5th inst. We offer our sincere sympathy to his relatives in the sad trouble which has fallen to their lot.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

QUACK AND CRIMINAL ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—To have the *Times* on one's side in an attack upon any evil or abuse is almost alone a guarantee of ultimate victory. You will have certainly the leading journal with you in your endeavour to arouse in newspaper proprietors and journalists a sense of their responsibilities to the public in the matter of the rampant quackery of the present day; and there need be no doubt that if you will persevere in the enterprise started in your excellent leader of to-day (Feb. 5), you will in the end compel many journalists—if only from shame—to follow the example displayed by their great contemporary. The *Times* has for many years acknowledged and tried to act upon the fact that there exists little difficulty in recognising the infamous rogues, whether unqualified practitioners falsely pretending to be legally qualified or concocters and vendors of nostrums and panaceas, who devote themselves to making money by the plunder of suffering humanity. The *Times* gives ample proof of its right motives in this matter, not only by occasional editorial utterances but by denying admission, at cost of vast pecuniary sacrifice, to the advertisements of many notorious quacks whose announcements find a place in all other newspapers. If the editors or proprietors of great journals like the *Standard*, the *Daily Telegraph*, and the *Daily News* are, as must be supposed, ignorant of the nature of the traffic they are abetting when they publish fraudulent quack advertisements, it is certainly their duty to inquire. These papers yield their owners princely incomes, they assume editorially the functions of censors of morals and guardians of the welfare of the people, they ought not for pay to stoop to aid, however indirectly, the cowardly wretches who live and flourish by preying upon the victims of nervousness and disease. If leading wealthy London journals show so bad an example, it cannot be wondered at that many others, more open to temptation, not only admit freely fraudulent advertisements of every class, but show themselves willing to sell their endorsement in the form of an editorial puff to any pretender who comes prepared, money in hand, to pay for it. Another class of papers, of which the *Echo* and the *Weekly Times* and *Echo* are perhaps the most conspicuous examples, devote themselves to the persistent disparagement of science, and of scientific medicine and surgery, and its practitioners. They destroy the confi-

dence of their simple-minded readers in medical men and their art, and prevent numbers of poor sufferers from availing themselves of treatment by which they might find relief or cure. The editors of such papers are quite within their rights in expressing views honestly held regarding the science and art of medicine; but in doing so they seem under a special obligation to keep their columns free from the advertisements of the army of cynical scoundrelism which lives by preying upon weak and ignorant invalids. It must be borne in mind that a large section of simple people look upon the appearance of an advertisement in a respectable newspaper as a voucher for the *bona fides* of the advertiser. This is more particularly the case when the paper is one which professes to devote itself especially to the exposure of humbug and fraud, or is the organ of some religious denomination. It would at present be difficult to name a single paper of either of these varieties which does not constantly insert numbers of advertisements that, to the eye of any man of the world, display the words fraud and falsehood plainly inscribed upon their faces.

I am, Sir, yours truly,

HENRY SEWILL.

Cavendish Square, February 5, 1902.

"SUPERFETATION."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I quite agree with Dr. Robert Hugh Hodgson's suggestion, regarding the usefulness of a discussion on superfetation, and at the same time I cannot see that by changing the term into "delayed development" we are clearing up the pathology of this anomaly.

I am, Sir, yours truly,

M. C. O'GORMAN, L.R.C.S.I.

[We cannot print any more letters on this subject.—ED.]

An American Quack at Birkenhead.

THE impunity with which unqualified persons are allowed to practise medicine in this country was demonstrated at an inquest held a few days since at Birkenhead on an old woman who died while being attended by one Pleavin, who claimed to be a medical graduate of Buffalo, Ohio. He admitted that he had never been in America though he claimed to have been passed an examination. He stated further that he had practised for twenty years, and had had patients "in all classes of society." He added that his certificates of death had been accepted during the past twelve years without question, a fact, if fact it be, which reflects anything but credit upon the local registrars. The jury returned a verdict of death from natural causes without passing any censure on the quack whose certificates, it may be hoped, will in future be received less readily than appears to have been the case hitherto.

Harvard Medical School.

MR. J. D. ROCKEFELLER proposes to give 1,000,000 dols. for the furtherance of the medical school at Harvard University, provided that other friends of the University raise about 500,000 dols. for the same object. It is stated that there is but little doubt that the condition will be speedily complied with.

Medical Sickness and Accident Society.

THE usual monthly meeting of the Committee of the Medical Sickness, Annuity and Life Assurance Society was held on 31st ult., at 429, Strand, London, W.C. In the absence of Dr. de Havilland Hall, the chair was taken by Dr. Major Greenwood, and there were also present Dr. J. B. Ball, Mr. H. P. Symonds, Mr. J. Brinsley James, Dr. Walter Smith, Dr. J. W. Hunt, Dr. Frederick S. Palmer, Dr. Alfred S. Gubb, and Dr. W. Knowsley Sibley. The Committee was principally engaged in examining special reports which are required once a year on the cases of members who appear to be permanently incapacitated. About a score of these reports were presented, and there is reason to fear that in most cases the members will never be able to resume professional work, and will continue to draw half sickness pay, usually 100 guineas a year, until they die. The accounts showed a gratifying

increase in the number of new entrants into the society, and a solid increase in the funds, which now amount to over £150,000. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33 Chancery Lane, London, W.C.

Two Scales of Fees.

A CURIOUS action has just been tried at Rothesay, N.B., in which Dr. J. B. Lawson sought to recover from the executors of a deceased lady patient the sum of £66 12s. for professional services. The curious point was that he had previously rendered an account in which his visits were charged at 1s. or 1s. 6d. each, whereas, on discovering that his late patient had been a person of means, he claimed to be entitled to charge 4s. per visit. In the result the Sheriff allowed the visits at the rate of 2s. 6d. each, disallowing all visits not vouched for by the plaintiff's visiting-book, so that judgment was given for £24, less the costs of the defendants.

A Wealthy Practitioner.

THE estate of the late Dr. Thomas Kidley, of Sheffield, has been valued at close upon £512,000, an amount which, it may safely be asserted, was not achieved in the practice of medicine. It is a matter for regret that not a single legacy appears to have been made to any charitable institution, medical or otherwise.

Neurological Society of London.

On February 6th, 1902, the following gentlemen were elected officers for the year:—President: Herbert William Page, M.A., M.C., F.R.C.S. Vice-Presidents: J. N. Langley, M.A., D.Sc., F.R.S.; S. J. Sharkey, M.A., M.D., F.R.C.P. Council: J. B. Lawford, F.R.C.S.; D. B. Lees, M.D., F.R.C.P.; C. Mercier, M.D., M.R.C.P.; W. Julius Mickle, M.D., F.R.C.P.; F. W. Mott, M.D., F.R.C.P., F.R.S.; J. S. Risien Russell, M.D., F.R.C.P.; James Taylor, M.D., F.R.C.P.; William Thorburn, B.Sc., B.S., F.R.C.S.; A. de Watterville, M.A., M.D., B.Sc.; W. Hale White, M.D., F.R.C.P. Treasurer: Charles E. Beevor, M.D., F.R.C.P. Editor of *Brain* (*ex-officio*): R. Percy Smith, M.D., F.R.C.P. Secretaries: W. S. Colman, M.D., F.R.C.P.; Henry Head, M.D., F.R.C.P., F.R.S.

The Dublin Sanitary Association.

THE Council of the Dublin Sanitary Association met on February 6th. The prevalence of small-pox in some of the English and Scotch towns, a daily communication with Dublin having been under discussion, the following resolution was unanimously adopted:—"That, as Dublin is at present threatened with an invasion of small-pox from London, Liverpool, Swansea, and Glasgow, and as mild cases are often mistaken for chicken-pox, the Council call upon the sanitary authorities of the city and adjoining districts to add chicken-pox to the schedule of notifiable diseases for the next six months."

Belfast Hospital for Sick Children.

THE twenty-ninth annual meeting of the subscribers of this hospital was held last week in Queen Street, the Lord Mayor presiding. The annual report stated that during the year 1901, 684 children were treated in the wards of the hospital, an increase over last year of 111. Of these 404 were medical, 269 surgical, and 11 eye and ear cases. Twenty eight deaths occurred, 22 in the medical and 6 in the surgical wards. Two hundred and seventy-two operations were performed. In the out-patient department 5,855 new cases were treated. Of these 3,002 were medical, 1,153 surgical, 1,071 eye and ear cases, and 629 dental. The total number of attendances of out-patients was 14,942, and 213 operations were performed; 187 children were treated in the Convalescent Home. The average expenditure per patient per day is 7½d. and the average number of beds occupied is 44, as against 8d. and 42½ last year. The total average cost per bed occupied is £44 10s., which sum is inclusive of the expenditure in the extern department. There has been a movement during the year to have an extension built to the hospital to accommodate twelve more beds, the cost of which would be about £200, but as this would entail an annual expenditure of £150 at least in addition to the present outlay, it was considered that the state of the finances did not warrant it, and the ques-

tion has been postponed for the time being, with the hope of obtaining more supporters and donations in the near future towards this much-felt want. The adoption of the report was moved and seconded, and the meeting shortly after adjourned.

Royal University of Ireland.

THE following Examiners were appointed for the year 1902 at a meeting of the Senate on February 7th:—Medicine: James A. Lindsay, M.D., Joseph F. O'Carroll, M.D.; Ophthalmology: Arthur W. Sandford, M.D., Louis Werner, M.B.; Midwifery: John W. Byers, M.D., Alfred J. Smith, M.B.; Medical Jurisprudence, &c.: Charles Y. Pearson, M.D., Antony Roche, M.R.C.P.I.; Materia Medica: Martin Dempsey, M.D., William Whitla, M.D.; Physiology: William H. Thompson, M.D.; Pathology: Edmond J. McWeeney, M.D., James Lorrain Smith, M.D.; Sanitary Science: Sir Charles A. Cameron, C.B., M.D.

Pass Lists.

Royal College of Physicians, Edinburgh: Royal College of Surgeons, Edinburgh; and Faculty of Physicians and Surgeons of Glasgow.

THE quarterly examinations of the above Board in Edinburgh were concluded on the 1st inst., with the following results:—

First Examination, Four Years' Course.—Of three candidates entered the following two passed: J. Q. Donald and D. Burrows.

First Examination, Five Years' Course.—Of eighteen candidates entered the following six passed: J. W. Pell, M. T. Naidu, J. L. Power, A. McMillan, Major Moody, and W. R. Miller; and seven passed in Physics, seven in Elementary Biology, and three in Chemistry.

Second Examination, Four Years' Course.—Of nine candidates entered the following six passed: J. Q. Donald, H. L. Jones, D. Burrows, W. Gerrard, J. O. Warwick, and E. H. Hunter; and one passed in Physiology and one in Materia Medica.

Second Examination, Five Years' Course.—Of twenty-six candidates entered the following twelve passed: M. S. Naidu, J. D. Kennedy, T. Owens (with distinction), T. F. Murphy, N. D. Sweetnam, W. H. Woodger, D. E. A. Buchanan, D. C. McCabe-Dallas, D. A. Hastings, J. Wylie, T. Archdeacon, and J. E. Purcell; and one passed in Anatomy.

Third Examination, Five Years' Course.—Of twenty-four candidates entered the following seven passed: D. Contractor, H. F. Everett, C. V. E. Naidu, J. G. Heathcote, H. Day (with distinction), J. Walker, and E. G. Taylor; and two passed in Pathology and five in Materia Medica.

Final Examination.—Of sixty-nine candidates entered the following thirty-three passed and were admitted, L.R.C.P.E., L.R.C.S.E. and L.F.P. and S.G.:—E. E. Turner, T. Huston, E. H. Kenny, W. E. Graves, W. McFarlane, H. B. Connell, J. E. George, E. Taylor, W. Barclay, S. A. Sittampalam, S. Rivers, G. E. Soltan, J. H. O'Sullivan, H. Aspinall, L. E. Staynes, R. G. Campbell, P. F. Manchester, M. Johnston, E. W. Kemp, E. Chisholm, C. L. Mandl, G. J. Harman, K. D. Contractor, (with honours); W. Hunter, C. E. Marshall, S. Ram Kapoor, D. E. Rees, G. Goldfoot, C. V. H. Naidu, K. Bonnar, J. J. McNicholl, W. Beck, R. Murphy; and fifteen passed in Medicine and Therapeutics; seven in Midwifery, and eight in Medical Jurisprudence.

Conjoint Examination in Ireland.

THE following candidates have passed the final examination of the Royal College of Physicians and Royal College of Surgeons:—J. F. Allen, V. F. Connor, P. N. Creagh, S. H. Curry, Miss Haidee Aleen Driver, A. Ellenbogen, W. N. Eustace, A. Tydd Mulhall, J. J. McInerney, C. J. O'Connell, C. R. M. Pattison, S. Potter, R. H. Ross, J. C. Ryan, J. P. Ryan, W. Scott, and S. A. Tucker.

Royal Colleges of Physicians and Surgeons of Ireland.

THE following gentlemen have passed the examination for the Diploma in Public Health of the Royal Colleges:—Thomas Hennessy, F.R.C.S.I., and David Mansfield Saunders, M.D., Major R. A.M.C.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

VACCINATION IN EXCELSIS.

It is perhaps a healthy sign when the lay public exhibit an equal enthusiasm for a prophylactic measure as do the antivaccinationists for its abolition. An amusing instance of this was shown at the annual meeting of the largest milk-supplying company in the metropolis a few days ago. When the chairman of Messrs. Welford and Sons, Limited, expressed a desire to receive suggestions from shareholders present, one enthusiastic believer in vaccination demanded that everyone connected with the company should submit himself to inoculation in order to reassure the public that the milk supply was not contaminated. The chairman gravely assured his questioner amidst much laughter, that he and each of his co-directors had already gone through the process, and that it would be extended throughout the staff to the cowboys.

G. T. TRUSCOTT (Trinidad).—(1) It would be well to have an examination of the blood made by a competent man. It is possible that the whole question of diagnosis would be thereby settled off-hand. (2) The fundus of the eyes had better be examined, as papillitis would indicate changes going on in the brain, and would strengthen the view that the seizure was of a true epileptiform character. At the same time kidney disease should be carefully excluded. (3) Temporary blindness occurs now and then—rarely in infants—independently of any optic nerve or fundus changes. It is an interesting phenomenon, but its exact causation has not been yet determined. The most probable explanation appears to be that there is some cortical or visual centre disturbance.

WESTON-SUPER-MARE. Statistics, as it is stated, "can be made to prove anything" although no doubt in the particular case mentioned every care is taken to ensure their correctness.

ANTITOXIN.—There is not any British degree of "Ph.D."; if our correspondent desires to acquire it he will have to apply to one or other of the German Universities which confer it. We have no knowledge of the conditions under which it can be obtained.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, FEB. 12th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m. Mr. J. Cantlie: Clinique. (Surgical.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Mr. C. P. White: The General Pathology of Tumours. (Erasmus Wilson Lecture.)

THURSDAY, FEB. 13th.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. F. W. Ramsay, Mr. R. O'Callaghan, and Dr. H. Macnaughton-Jones. Dr. H. Croom (incoming President): Inaugural Address.

FRIDAY, FEB. 14th.

CLINICAL SOCIETY OF LONDON (20, Hanover Square, W.).—8.30 p.m. Papers:—Mr. G. Barling: Seventy-four Cases of Appendicitis with Localised Surgery, with special reference to the treatment of the appendix in such cases. Mr. F. C. Wallis: The Treatment of Intra-peritoneal Abscess of the Appendix, illustrated by cases.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Mr. C. P. White: The General Pathology of Tumours. (Erasmus Wilson Lecture.)

DUBLIN.

FRIDAY, FEB. 14th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of State Medicine. 8.30 p.m. at the Royal College of Physicians. Agenda:—1. President's Address. 2. Case of Lead Poisoning. 3. H. Gray Croly: On the Disposal of Surgical Dressings, &c. 4. E. J. McWeeney: Concluding Remarks on the Milk of Tuberculous Cows.

MONDAY, FEB. 17th.

ROYAL COLLEGE OF SURGEONS.—Examination for Fellowship commences.

Appointments.

CANE, HOWARD, M.D., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Staff at the Crossness Outfall Works.

DONALD, W., M.D.Aberd., Certifying Surgeon under the Factory Acts for the Banff District.

FIRTH, J. LACY, M.D., M.S.Lond., F.R.C.S.Eng., Surgeon to the Bristol General Hospital.

HAMILTON, J. STIRLING, B.A.Cantab., House Physician to St. Bartholomew's Hospital.

HULBERT, H. L. P., M.A.Cantab., House Physician to St. Bartholomew's Hospital.

KERR, JAMES, M.D.Cantab., Medical Officer to the School Board for London.

LITTLE, A. J., L.R.C.P.Irel., L.S.A., Medical Officer of the Uxbridge Union.

MATURIN, H., M.R.C.S., L.S.A., Medical Officer of Health for the Hartley Wintrey Rural District, Hampshire.

NICHOLSON, BALFOUR STEWART, M.B., M.S.Glas., Medical Officer of the Parish of Clackmannan.

PINKER, H. G., M.R.C.S., L.R.C.P., Intern Midwifery Assistant at St. Bartholomew's Hospital.

SHENNAH, THEODORE, M.D.Edin., F.R.C.S. Edin., Superintendent Pathologist to the Edinburgh Royal Infirmary.

THOMAS, A. E., M.B.Lond., House Physician to St. Bartholomew's Hospital.

URWICK, R. H., M.A., M.B., B.C.Cantab., House Physician to St. Bartholomew's Hospital.

WEIR, H. H., B.A.Cantab., House Physician to St. Bartholomew's Hospital.

Vacancies.

Ashton-under-Lyne, District Infirmary.—House Surgeon. Salary £120 a year, with board and lodging. Applications immediately to William Bottomley, 120 Stamford Street, Ashton-under-Lyne.

Clogher Union.—Medical Officer for the Workhouse. Salary £100 per annum. Immediate application to Thomas Turner, Clerk of Union. (See Advt.)

County of Caithness.—Medical Officer of Health.—Salary £250, and £50 for travelling and other expenses. Applications to James Brims, County Clerk, Thurso.

Durham County Hospital.—House Surgeon. Salary £100 a year and board and lodging. Applications immediately to W. E. Wilson, Secretary, 68A Sadder Street, Durham.

Durham County Asylum.—Junior Assistant Medical Officer. Salary £140, with board, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Edenderry Union.—Medical Officer. Salary £120 per annum, and £25 per annum as Medical Officer of Health. Immediate application to T. Humphrey F. Dor, Clerk of Union. (See Advt.)

Fisherton Asylum.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to Dr. Finch, the Asylum, Salisbury.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £30 per annum. Applications to S. J. Leonard, Clerk to the Hospital. (See Advt.)

Kent and Canterbury Hospital.—House Surgeon. Salary £100 a year with board and lodging. Applications immediately to A. J. Lancaster, Secretary.

Royal City of Dublin Hospital.—Resident Medical Officer. Immediate application to G. Jameson Johnston, Hon. Sec.

South Africa—Cape Copper Co., Ltd.—Qualified Assistant to act as Dispenser and Assistant Chief Medical Officer. Salary £180 per annum. Address, by letter only, Secretary, Cape Copper Co., Ltd., 9 Queen Street Place, E.C. (See Advt.)

Stockport Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, and laundry. Applications immediately to the Secretary.

Suffolk County Asylum.—Second Assistant Medical Officer. Salary commencing at £130 per annum, with board, lodging, laundry, and attendance. Applications to the Medical Superintendent, County Asylum, Melton, Suffolk.

Warneford Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and apartments. Applications to the Secretary.

Births.

BENNETT.—On the 30th ult., at 22 Broad Street, Birmingham, the wife of W. Edward Bennett, F.R.C.S.Eng., of a daughter.
FRERE.—On Feb. 6th, the wife of A. Hasbury Frere, M.B., of The Nunnery, Diss, Norfolk, of a son.

Marriages.

POPE—ROPER.—On Dec. 12th, at Kroonstad, O.R.C., Francis Pope, M.R.C.S., L.R.C.P., of Birmingham, to Nancy, third daughter of C. E. Roper, of Blisworth, Northamptonshire.

TATE—SIMPSON.—On Feb. 5th, at the Parish Church, Loversall, by the Rev James C. Ross, George Temple Tate, M.D., elder son of the late George Ralph Tate, M.D., A.M.S., to Janet, younger daughter of William Simpson, Esq., of Loversall, Doncaster.

Deaths.

BEAMAN.—On the 6th inst., at Bridge House, Setch, King's Lynn, Joseph Harrison Leonard Beaman, M.A., M.D., I.M.S., 28th Bombay Pioneers, aged 29.

BLATHERWICK.—On Feb. 6th, at his residence, 4 Queen's Mead Road, Bromley, Kent, Deputy Surgeon-General Thomas Blatherwick, in his 79th year.

COPPIN.—On Jan. 31st, at 181 High Street, Plumstead, Mornay Coppin, M.R.C.S., in his 90th year.

DAVEY.—On Feb. 5th, at 18 Granville Place, Portman Square, W., Francis A. Davey, M.R.C.S.E., L.S.A., late of Barkway, Royston, Herts., and third son of the late William Davey, of Welton Lodge, Lyncombe, Bath.

LANKESTER.—On Jan. 30th, at Salisbury Road, Leicester, Henry Lankester, M.R.C.S., L.S.A., J.P., aged 76.

SLAUGHTER.—On Feb. 3rd, at Woodlands, Horeham Road, Sussex, Charles Henry Slaughter, Esq., Inspector-General of Hospitals and Fleets, Royal Navy, second son of the late Dr. T. G. Slaughter, of Farningham, Kent, in his 68th year.

STOWERS.—On Feb. 3rd, at Clapham Road, S.W., well Stowers, M.R.C.S., in his 87th year.

A CASE OF SCLERODERMIA ASSOCIATED WITH RAYNAUD'S DISEASE. WITH SPECIAL REFERENCE TO TREATMENT. (a)

By WILLIAM EWART, M.D. Cantab., F.R.C.P.,
Senior Physician to St. George's Hospital, and to the Belgrave
Hospital for Children.

THE special group of cases of diffuse sclerodermia of which this patient is a good representative, is of interest, as it presents prodromata which are almost as remarkable as the disease itself, and which we cannot afford to overlook in connection with ætiology. The beginnings of sclerodermia are insidious, and the variety of its alleged determining causes is such as to make us doubt whether any of them are true causes. But in some cases the occurrence of well marked symptoms of Raynaud's disease carries with it a definite suggestion as to ætiology. Vidal (b) long ago propounded the view that the earliest beginning was a vasomotor disturbance, at first functional, but ultimately leading to obliterative periarteritis.

If we admit varieties in the type of the disease we may also imagine different modes of origin for it. E. Jeanselme (c) makes a distinction between cases of acute development and those more slowly and widely spreading. The latter he regards as hardly capable of recovery. He believes that obliterative endoperiarteritis is the starting-point of the cutaneous sclerosis. F. X. Dercum (d) recognises (1) an oedematous form, (2) an indurative form, and (3) a form without infiltration. Possibly, however, the varieties described may be rather differences in degree of severity, in stages of development, or in duration, than differences in kind. On that supposition the vasomotor phenomena, when they are seen, even assuming them to be merely correlated rather than causal factors, indicate a strongly nervous bias in the mechanism of the disease, and the group in question might be the means of identifying this mechanism as a trophoneurosis.

All modern writers call attention to cases of this kind. Sir Thomas Barlow (e) refers to instances in which Raynaud's symptoms were the precursors of sclerodermia. But in Dr. Finlayson's case, which he quotes, the patient suffered from symmetrical gangrene at a late stage of his sclerodermia, as though the usual order had been reversed.

Possibly here, as in many previous instances, the original milder symptoms of Raynaud's disease may have been overlooked. Many years ago, a young woman was under my treatment for unexplained attacks of local oedema and faintings. She ultimately developed sclerodermia, for which she was again for long periods an inmate in the hospital, and she finally recovered. The same sequence was observed in the following case, a brief account of which may prove of interest.

Case.—M. G. H. (a), married (three miscarriages, but no children), was admitted into St. George's Hospital on January 2nd, 1902 ("Med. Reg.," No. 4, 1902), complaining of tightness of the skin and of coldness of the extremities, vomiting, and other symptoms. No facts of importance were elicited in the family history. Her own clinical record was one of some constitutional delicacy but of few acute seizures. Her habits are temperate, and there was no evidence of syphilis. At the age of eighteen she suffered for five months from anæmia and flatulent dyspepsia which were relieved by the extraction of several bad teeth. She had quinsy seven years ago, but no other serious illness. Six years ago she began to suffer from coldness and blueness of the fingers and toes, chiefly during the winter, and her digestion again gave way, and has remained unsatisfactory. The circulation in the extremities became gradually worse, the blueness of the fingers occurring in the summer as well as in the winter during the last two years. For this condition, and for an attack of menorrhagia which Dr. Stabb traced to a threatened or incomplete abortion, she was an in-patient under Dr. Lee Dickinson from November 29th to December 13th, 1900 (St. George's Hospital "Med. Reg.," No. 1,796, 1902). She was then found to be suffering from Raynaud's disease, and in addition Dr. Lee Dickinson detected early indications of sclerodermia. The notes also make mention of pain in the right wrist, and of pain under the left nipple. The symptoms showed some improvement during her stay in the hospital, where she was treated with strychnine and other tonics.

Since then, but chiefly during the last six months, there has been a progressive deterioration. Six months ago the vomiting and retching to which she had occasionally been subject became much worse, and she first noticed an uncomfortable tightness of the skin. During a short stay at Eastbourne she became a little stronger, but the skin did not improve, and has since become worse. She remained liable to flatulency and to attacks of pain below the heart, with faintness, and with vomiting of fine white froth. On three occasions the retching brought up about a teaspoonful of blood.

At the time of her present admission, in addition to these symptoms, the "tightness" which she had

(a) For the history of this case I am indebted to Dr. Stokes, Medical Registrar.

noticed for the last six months, but which had greatly increased during the last three months, was such that she could not use her fingers, which were stiffened in a slightly flexed position, and the wrists were also stiff, and in a less degree also the shoulders. The movements of the lips were impeded. Owing to the stiffness of the skin of the back she could not stoop so as to reach her feet. She states that she has been forgetful and "slow" lately.

On examination she is thin, and presents the characteristic pinched sclerodermial features; the skin of the face is drawn, dry, and branny, but not absolutely pale; the nose sharp, the lips stiff and tightly drawn, exposing part of the upper incisors; the upper lids also heavy and stiff, but they meet the lower lids; but the palpebral aperture, like that of the mouth, appears to be slightly shortened. The hair, which has been falling a good deal, is dry and rather harsh, but fairly thick. The skin of the back is somewhat inelastic, but shows no other marked change. On several of her fingers are cicatrices of old ulcerations. These always began gradually, and were difficult and slow to heal. The fingers are pointed, the skin of the phalanges thick, shiny and hard, and cannot be pinched up, and this condition extends in slighter degree up the wrists, which cannot be flexed, particularly the left. The fingers, which are partly bent, cannot be completely extended, neither can they be flexed into the palm. The skin of the hands and that of the cheeks, nose, and lips is typically sclerodermic, but that of the back, of which she complained so much, is not obviously hardened. The feet are cold, the toes bluish, but free from ulcerations or cicatrices. The only necrotic ulcer—and this is now healing—is on the edge of the right thumb. She states that the left leg often swells but there is no swelling now, and no oedema elsewhere. The neck is thin. The thyroid isthmus can only just be felt.

The chest is spare; the mammae rather flattened with prominent nipples. The tightness is felt by her chiefly on the left side between the shoulder-joint and the left mamma.

The organs are found to be apparently healthy. There is no cardiac murmur. The apex beats in the nipple line. Respiration quick. Pulse small, about 80 per minute. Temperature slightly subnormal. Urine normal. The knee-jerks are markedly exaggerated, the plantar reflexes active.

The progress of the patient under treatment has been one of steady improvement, the details of which will be gathered from the following observations.

REMARKS ON THE CLINICAL AND THERAPEUTICAL ASPECTS OF THE CASE.

To sum up the case, it is not obvious why the patient should have lapsed from her former standard of health, but the special history of the symptoms is fortunately nearly complete. The genuineness of the case as one of Raynaud's disease was fully tested at the date of her first admission under Dr. Lee Dickinson. At that time local syncope was a feature, in addition to local asphyxia. When readmitted under my care, further evidence was afforded by the daily attacks of local asphyxia in the fingers and toes, by the small necrotic ulceration, which has now healed to a scar, on the ball of the right thumb, and by the minute scars left on all the finger tips by previous ulcers of a similar kind.

As regards the cutaneous condition, although she dates the onset of the stiffness to six months ago, the earlier beginning of it had not escaped Dr. Lees Dickinson's observation. He noted so far back as December, 1900, the characteristic sharpness of the features, the bridling of the lips, and the slightly bent attitude of the fingers, and although others

could not then agree with him in recognising scleroderma, the correctness of his diagnosis has since then been proved. The husband had noticed even earlier changes. Four years ago the facial expression began to alter and the face became "much smaller." Thus the case is no less genuine as one of scleroderma. As she appears to-day she still displays many of the features of that affection, although they are quickly vanishing. The mouth, which on admission was incapable of much movement and the lips unable to meet, is now equal to proper articulation and to the movements of smiling and of whistling, and the line of teeth is no longer exposed. The fingers which could not be flexed are now readily closed and extended, and the wrists are much less stiff. The feet have likewise improved. Little change had fortunately occurred in the trunk, except a stiffness and tightness felt at the back of the shoulders and down the front of the left axilla. The breasts are still rather flat, and the nipple made prominent, but in every part the skin is gaining in suppleness and mobility, and there is no fresh extension of the scleroderma.

Lastly, the genuineness of the third pathological element in the case is sufficiently declared by the severity of the recurrent gastric attacks. The dyspepsia and the malnutrition arising from it might indeed be regarded as the chief ætiological factors, but it is also possible to conceive that the stomach as well as the heart may have suffered secondarily. In this respect also the amendment has been most marked and rapid.

I may now be allowed to briefly review those peculiarities of the case which present a practical bearing upon treatment and ætiology.

1. The liability to *local asphyxia* need not be again insisted upon.

2. *The malnutrition.*—The wasting of the muscles in this disease may be to a great extent explained by disuse. But the loss of fat which is one of its known features may be regarded as proof of an alteration in the metabolism, inasmuch as rest often breeds fat and rarely wastes it. The patient presented on admission this peculiarity and the mal-nutrition in this direction led me to inquire into the state of the thyroid gland.

3. *The thyroid* has in some cases been reported as atrophied. In this patient it is certainly unduly small, though it may just be felt. This peculiarity has much importance as a suggestion in the direction of ætiology and of treatment.

4. The question as to *rheumatism* or any other toxæmia should always be investigated. Rheumatism is mentioned in some reported cases, and endocarditis, which may have been rheumatic, in others. In the present case there is no history of any rheumatic attack. But there was partial fixation of both wrists, chiefly the left, where some teno-synovitic crackling was obtained, and some adhesions had to be broken down before free movement was restored.

5. *Pigmentation*, or loss of pigment, which are often observed, were not present here. There was neither pigmentation nor leucoderma.

6. *Disturbances of the nervous system*—cerebral, spinal, or sympathetic—have not been prominent in this patient. There were no mental symptoms, nor hysteria, nor any obvious failure in nerve conduction. The knee-jerks were markedly exaggerated.

7. *The visceral functions* were not, however, absolutely perfect in connection with sympathetic innervation. Dyspepsia may well be expected in one partly paralysed in the lips and jaws, and the occurrence of pain felt at the region of the heart and associated with flatulency may be at least partly referred to a nervous origin.

8. A special feature which may be more frequent

than hitherto suspected, was the tendency to cardiac depression and syncope. During the interval between her two attacks, pain at the heart and flatulence were a frequent complaint; but she has only once suffered in that manner since her admission. I have regarded this symptom as pseudo-anginal, and this view is not negatived, but perhaps supported by the fact that the pain has usually been relieved by a discharge of flatus. The occurrence of some degree of cardiopathy in sclerodermia of the Raynaud type is after all nothing more than may be expected where the vascular system is so unduly sensitive, and where the peripheral vascular resistance is demonstrably increased. The precise nature of this cardiac reaction I will not venture to discuss. It may be toxic or vasomotor and may affect the nutrient vessels of the heart or its constituent muscles and nerves. Another important point in symptomatology is that in this case the attacks of peripheral asphyxia were apt to occur soon after meals. This suggested another etiological mechanism for the vasomotor change, that of visceral irritation.

THE TREATMENT OF THE CASE.

The treatment was planned according to the leading features which have just been mentioned, and largely as it will be seen on the lines of hygiene rather than of medication.

The nutritional indication was the first to receive attention, and, as a foundation for further treatment, rest in bed and an easily digestible liberal diet were ordered. Subsequently the patient was allowed six ounces of port wine daily.

Next to feeding the patient most importance attaching to a protection of the peripheral circulation, I had intended to keep the hands and wrists immersed in warm oil; but in the absence of suitable hand baths I caused the hands to be oiled freely and covered with protecting gloves, and each hand to be kept night and day enclosed in a bag containing a hot water bottle surrounded with cotton wool. This had the effect of breaking through the habit of the recurrence of the cyanosis each morning, much to the patient's comfort. The oil used was a mixture of equal parts of almond oil and olive oil with 5 per cent. of oil of eucalyptus.

To influence the thickening and stiffness of the skin, passive movement and massage with oil were applied at intervals to the arms and hands and to the upper part of the chest and back.

On January 4th, thinking that diaphoretics and peripheral vaso-relaxants might help the skin, a mixture was ordered to be taken every four hours containing Liq. trinit. Mj, Haust. am. acet., ad 3j, and the use of thyroid extract which she had taken for two days since admission was discontinued. The skin, as stated, had hitherto been dry and rather harsh. On January 7th Sp. æther. nit., 3j was added to the dose, and special skin massage was applied to the hands and feet. On January 8th the patient was encouraged to practise for herself movements of the fingers. On this date a decided improvement in the conditions of the skin, in its sensation, and in its mobility were apparent. On the 9th, the nitroglycerine having been well borne hitherto, the dose was increased to 1½.

A further instalment of treatment was now begun specially intended to remedy the deficiency of subcutaneous fat; 2 ozs. of olive oil and ½ oz. whisky were ordered to be taken every night, in spite of the patient's objection that she could not swallow any oil. The dose had to be reduced on the 11th to ½ oz. of oil with a drachm of whisky, and this she was able to keep down, and persevered with regularly. She is now taking 1 oz. of oil and ½ oz. of whisky. On January 14th a 4-grain Pill Hyd. c. Rh. was ordered

every other night to facilitate the digestion of the oil.

The improvement now went on at a great rate, and I turned more special attention to the hygiene of the muscular system, and taught the patient the respiratory exercises suited to bed-ridden cases. The dose of the Liquor trinit. was raised to 2 minims, but had to be reduced again on the 17th to the previous amount owing to headache. It may be mentioned that on the 14th, the weather being rather colder, some cyanosis was experienced again, and there was some faintness while she was sitting up. The catamenia began this day and lasted for three days.

On January 9th sweating had been observed for the first time over the epigastrium and back, and the next day she felt much better, with less stiffness in the fingers, but still some cyanosis.

January 12th was the first day when no cyanosis occurred.

Throughout this period the improvement had been steady and relatively rapidly.

On January 29th the following note was made:— "She had been getting up every afternoon since the 17th. She is now much better, and can stoop quite easily. She can raise her arms above her head. The lips are kept habitually closed. She can smile and whistle. The skin of the feet feels much more comfortable to the patient, indeed, quite loose; the improvement in this direction is the more noteworthy as no local treatment, except a hot-water bottle and massage, was applied to the feet. The fingers have lost a great deal of the hard, waxy, leathery appearance, and it is possible to lift the skin to a certain extent even off the phalanges. The fingers can now be freely flexed and the fists doubled; and it has become possible to dispense with the continuous local application of warmth. There is, however, some remaining stiffness of the wrists, particularly of the left. This can be overcome by forcible, passive movement, but not without the feeling and sound of breaking down fine adhesions. There is also up the back of the wrist, along the sheath of the extensor tendons, a very perceptible crackling, as of teno-synovitis, on movement. After these manipulations, which had to be repeated, the mobility of the wrist has gradually improved. The patient's face has lost some of its sharpness, and presents a more oval outline. A deposition of fat is also noticeable in almost every part of the body, except, however, the breasts."

REMARKS ON THE PATHOLOGICAL ÆTIOLOGY OF SCLERODERMIA.

The treatment had been based on the hope that the affection might be, at any rate in this case, an essentially functional one; its results so far seem to justify that view. On the other hand, in other cases definite structural changes have been described. Whether it be that diffuse sclerodermia is not always one and the same, or that at times a greater intensity or a longer duration of the affection may be apt to damage the tissues, instances of the following lesions have been recorded in addition to obliterative arteritis (a), viz., an increase in the elastic network, a hypertrophy of the smooth muscular fibres, a cell proliferation within the adipose tissue, a pigmentary infiltration, some increase in the fibrils of the connective tissue, but little or no change in the nerve fibrils or their sheaths.

It is noteworthy in connection with these changes that the disease is not one belonging to the degenerative stage of life. Rarely witnessed before ten, it usually occurs between the ages of twenty and forty (Dercum). Neither the blood nor the urine have

(a) cf. Jeannelme loc. cit. cf. also Lewin and Heller "Die Sclerodermie." Berlin, 1895.

been found materially altered. Although the latter has been described as lessened in amount, the kidney as well as the other viscera are probably free from any marked structural changes.

Whilst recording these findings it is right to add that some of the changes may in part be secondary to the mechanical interference with the circulation. For instance, the proliferation of the connective tissue cells may be analogous to that which takes place in the pseudo-elephantiasis of inveterate lymphatic or simple venous cedemas. In the same way adhesions may ultimately, as in this case, form in or around a joint which was originally fixed by cutaneous stiffness.

Among the possible primary structural lesions special mention should be made of the alleged atrophy of the thyroid. The profound alterations in the circulation witnessed in some forms of thyroid disease might be used as an argument in favour of a thyroid origin of scleroderma. Rapidity of pulse and cardiac palpitations (*Dercum*) have sometimes been noted, and scleroderma has been known to occur in the course of Graves' disease. At the same time we should not lose sight of the possibility that the thyroid and its functions may be involved secondarily; and until further evidence has been obtained from trustworthy observations made at an early stage of the disease the thyroid origin of scleroderma must be regarded as a mere theory. According to that theory it has been suggested that scleroderma might arise from some fault in the supply or from some modification in the composition of the collagen of the skin analogous to the alteration in the mucin in myxœdema; or the induration might perhaps be regarded as a stiff myxœdema from dehydrations of mucin in the ischæmic areas. Whilst these are mere speculations, it is probable that the lymphatic circulation is much impeded in the parts affected.

It is obviously premature to draw any general conclusions, but the conjunction of Raynaud's disease with scleroderma is an important fact which should cause us to look for some broader ætiology capable of explaining both the vascular and the cutaneous phenomena. The present case lends colour to the view that Raynaud's disease, as well as scleroderma, are essentially functional rather than structural. The patient's improvement under treatment seems to prove that the obliterative arthritis of Friedländer was not present in this case, and that if it should occur in other cases this may be a complication or a late development rather than an early mechanism.

As regards *prognosis*, the rapid improvement in this case supports the view borne out by the later history of some other chronic cases that the disease may be recovered from. I am inclined to think that it ought to be recovered from if our treatment were adequate. This is also borne out by the fact that the early case to which I referred ultimately recovered. The disease in itself, putting aside its cardiac complications, has nothing of a fatal tendency except in the malnutrition due to mechanical interference with many of the functions and in the resulting depression of vitality. It is not to be wondered that the liability to fatal pulmonary and renal complications should be considerable; but if these and other complications can be avoided recovery may eventually occur even in aggravated cases and after a prolonged duration.

ACCORDING to our all-knowing contemporary, the *World*, "All the Cabinet have been vaccinated. Lord Londonderry and Lord Ashbourne are both nursing their arms, and among others Lord Roberts has suffered much." Would that the example of "vaccination in high life" might dissipate all conscientious objections in the lower ranks of society.

THE TREATMENT OF PLEURAL EFFUSIONS. (a)

By ARNOLD CHAPLIN, M.D., M.B.C.P.,

Physician to Out-Patients, City of London Hospital for Diseases of the Chest.

THIS question of the treatment of effusion is of especial interest and importance to the practical physician, inasmuch as it is met with frequently in practice, and because, if properly treated, there are few diseases which bring the physician more credit. Before our great clinical master, Trousseau, explained the conditions which necessitated the evacuation of fluid in the chest, pleural effusion was regarded as a most grave disease which might easily compromise the safety of the patient. At that time a fierce controversy was waged over the question as to whether it was right to tap a chest containing serous fluid under any conditions. Collapse of the lung, pneumothorax, empyema, and syncope were asserted to be the almost certain results of such a proceeding. But Trousseau, and those with him, paid no heed to such warnings, they continued to tap effusions, with such good results that under certain conditions the practice became established on a firm foundation, and the controversy which the method evoked is now only of academic interest. The advantage of tapping an effusion was so manifest, under certain conditions, that for many years the tendency was to tap any effusion almost regardless of the presence or absence of the indications for tapping; and I am not sure that, even at the present time, effusions that would get well admirably without the trocar, are not aided or retarded by tapping. Perhaps the simplicity, the ease, and the safety of the operation all lend themselves to the natural impatience of human nature, and determine us to expedite matters instead of awaiting Nature's own good time.

For the purpose of discussing the treatment of this disease I propose to classify pleural effusion under two heads, namely, simple pleural effusion and pleural effusion complicated with some other conditions of chest disease. By the simple form of pleural effusion I understand that resulting from an attack of pleurisy in an otherwise healthy person, independent of any disease of the lung, often rightly or wrongly attributed to catching a cold or chill. As to the question of this effusion being tuberculous or not, I do not think the scope of this paper offers facilities for its discussion, and indeed, for purposes of actual treatment, it does not matter. This simple pleurisy runs for the most part a perfectly definite and normal course. The effusion goes on increasing for a time, then remains stationary, and eventually becomes absorbed, leaving nothing but adhesions, and to all intents and purposes the patient is as well as before. It has often been said that simple pleural effusion is a disease which lasts about six weeks, and I do not know that the amount of the effusion alters in any great degree the duration of the disease. Another point of interest in simple pleural effusion is that it has frequently been noticed to have a particular affection for the left pleural cavity. Indeed, in my own practice so often have I observed this that I have grown to regard left-sided effusions as more likely to be independent of any serious lung condition than right-sided ones. With these few remarks as to the clinical history of simple pleural effusion we may, I think, pass to the consideration of its treatment. It will, perhaps, be most convenient to first discuss the treatment of simple pleural effusion by means of drugs. The catalogue of drugs used to allay the inflammation and promote the absorption of the effusion is a lengthy one, and it is difficult to find any common agreement as to their use. We may enumerate such drugs as acetate of ammonia, nitrate of potash, squills, digitalis, acid tartrate of potash, and juniper and scoprium, among those employed to promote excretion by the kidneys and skin; iodide of potash and iodide of iron among those given to promote absorption; arsenic, iron, quinine, and mercury as tonics and alteratives. Again, as local applications, iodine and blisters

(a) Read before the Harveian Society, January 22nd, 1902.

are frequently prescribed. Strapping is also used by many to keep that side of the chest quiet, and so arrest pain. With regard to these drugs, given in order to promote excretion by the kidneys and skin, it is difficult to say that they have ever exerted any appreciable effect in lessening the amount of the pleural fluid. Iodide of potash and the syrup of iodide of iron have, on the other hand, been frequently spoken of as being of great use when the fluid has been stationary for some time, and when there has been evidence of its having become thick and inspissated. As common practice I have treated limited pleural effusions with either iodide of iron or iodide of potash combined with quinine, and experience seems to show that resolution of the fluid is hastened by the exhibition of such drugs, when compared with the time taken for similar effusions to resolve without any drug treatment. With regard to the local application of iodine and blisters, all are agreed as to their efficacy in relieving pain and uncomfortable sensations, and some claim that they largely assist in promoting the absorption of the fluid. It must be confessed, however, that the way in which they do this is by no means clear. The treatment by rest and diet is of great importance in pleural effusion; all are agreed as to their value. The patient should be kept rigidly in bed and as much as possible on his back, all sudden movements, such as sitting up in bed should be guarded against, for not a few cases are on record where fatal syncope has resulted from suddenly sitting up in bed, though it is right to state that in most of the cases given, the pleural effusion was large and of rapid onset. The practice of giving low diet and a reduced quantity of fluid is to be commended, and is usually followed. During the inflammatory stage of the attack, much discomfort may be avoided by strapping the chest. But this must not be persevered in too long, for when the fluid is ripe for absorption, free movements of the chest are of the utmost importance in promoting the resolution of the fluid. By such simple methods very many pleural effusions will get well, and leave no trace or at most some thickening of the pleura and adhesions. In many instances, however, this expectant form of treatment does not have the desired result, and in spite of everything we can do the effusion increases or remains stationary. We are then face to face with the large question of tapping, and it is to this question of tapping that I would particularly draw your attention. Let us for the purpose of discussion, divide the practice of tapping in simple pleural effusions, into two parts, namely, *When to tap* and *How to tap*.

1. *When to tap*.—The rule used to be laid down and very generally followed, that unless there was evidence of pressure in the pleural cavity, causing dyspnoea, rapid and weak pulse, and considerable displacement of the heart, tapping was unnecessary. By following this rule many cases of simple pleural effusion, of large extent, but giving no signs of causing distress, nor showing any tendency to become absorbed, were left week after week, until the disease became one of months rather than weeks. Practice then went to the other extreme, and many were in the habit of tapping almost any collection of fluid in the chest, giving no time to Nature to effect the cure. Under these circumstances, no wonder that observers were unable to see any real benefit from tapping. Then, again, some confusion as to the results of tapping has arisen, owing to the fact that it is not made clear that there are two distinct ends to be obtained. When a patient has his pleural cavity full of fluid, and is in great danger from the pressure exerted, tapping is resorted to to relieve a dangerous condition. When, on the other hand, a pleural effusion shows no signs of being absorbed, tapping becomes a means towards curing the patient of his trouble. Therefore, I would lay it down that tapping the chest is indicated: (1) When dangerous symptoms arise from the pressure of the fluid. (2) When Nature gives no sign of removing the fluid by the means at her disposal. Under any other condition I hold tapping to be useless, and only calculated to bring a much prized method into contempt. To make this clearer, let us suppose that one has to deal with a case of pleural effusion in which one side of the chest is two-thirds full of

fluid. The patient has no distress, the disease is but a few days old. The pleural cavity is evacuated by means of the trocar, and with what result? The condition of the patient is in no wise improved. The temperature continues its irregular hectic course and in a few days the chest is again as full as ever. In this instance the tapping has been resorted to while the inflammatory process was still going on. Had there been, however, severe distress and dyspnoea the tapping would have given immediate relief, and if the chest again filled up causing distress the same process might be again repeated, always with the assurance that the injurious symptoms for which it was performed would be relieved. Similarly, there can be no good purpose served by tapping an effusion which is showing signs of being absorbed, but when after some time the effusion is just as much as ever, judicious tapping will hasten recovery considerably. By some it is claimed that if tapping has to be done at all it curtails the duration of the disease. To this doctrine I am unable to subscribe, unless it be limited to the tapping of a full pleural effusion at the end of the disease, which, for some reason or other, is sluggish and shows no sign of disappearing. My experience points to the fact that early tapping to relieve dangerous symptoms does not in any way shorten the duration of the disease.

To sum up then the main points in the question of when to tap. 1. Paracentesis may be required to relieve urgent symptoms, such as dyspnoea and syncope. This necessity generally arises during the early or inflammatory stage of pleural effusion, and consequently one must not be surprised if the pleural cavity fills up again. 2. Tapping is necessary when the fluid shows no signs of disappearing, and if properly performed there is no reason why the pleural cavity should fill up again. 3. Paracentesis does not appreciably shorten the duration of the disease unless performed after the inflammatory stage has passed.

We will now pass to a consideration of the question of how to tap. The old clinicians with primitive methods obtained excellent results by the simple means of inserting a trocar into the pleural cavity and allowing the fluid to run away at will. But soon cases came to be recorded in which air had been introduced into the pleural cavity and pneumothorax established, or the serous effusion converted into pus. To obviate this Trousseau adopted the expedient of fixing on to the end of the trocar a piece of goldbeater's skin. This acted as a valve, and permitted the fluid to run out, but closed against the ingress of air.

As to the question of pneumothorax being produced, on two occasions I have seen it as the result of inserting a trocar. The operation was performed by a medical man, who took every precaution, but the layer of fluid was so thin that he punctured the lung. After a few hours all the phenomena of pneumothorax supervened, but with this difference, that the patient experienced no distress. The symptoms remained for about four days, and then entirely disappeared. A second tapping was resorted to, but the fluid was still serous, and the patient made an excellent recovery. In fact, I have always thought that pneumothorax produced in a pleural cavity with pleura capable of healing again is but a trivial condition.

When, in the old days, pus was found in the pleura soon after a tapping, I take to be due to the want of proper antiseptic precautions, such as a dirty needle, rather than due to the entry of air into the pleural cavity.

Another question as to the production of pneumothorax occurs: If the fluid will run out of a trocar by the lung expanding, how can air enter in? In fact, in the laboratory it is most difficult to produce artificial pneumothorax.

Soon after the simple trocar, one with a length of rubber tube was introduced, and for many years the chest was evacuated by means of syphoning. Difficulty was, however, often met with in this method. The fluid after flowing freely for a time would stop, although the pleural cavity was by no means emptied. The practice at that time was to tap every effusion, and to completely empty the pleural cavity. So the aspirator was brought into use, and owing to the ease with which an effusion could be completely dissipated, soon gained universal

acceptance. But I cannot help thinking that had the true principles which govern paracentesis been thoroughly grasped, the use of the aspirator would never have gained such popularity as it now possesses. In the early stages of pleural effusion, when paracentesis becomes imperative to relieve dangerous symptoms on account of the great quantity of effusion, syphoning will remove the fluid just as well as aspiration. It is only in the later stages of the disease, when the lung is bound down, has lost its resiliency and cannot expand to drive out the fluid, that the aspirator offers special advantages over the ordinary trocar. When using the aspirator there is also always the possibility that the pressure exerted is too much, and acts too quickly, thus not allowing time for the lung to take the place of the withdrawn fluid; in other words, creating a partial vacuum in the pleural cavity. In this case the partial vacuum must be filled with something, and if the lung cannot expand, the re-filling of the cavity with fluid is the natural result.

From these considerations it is therefore claimed that the right practice in tapping pleural effusions is to use the syphon where possible; it is safer and, in but a few special cases, acts as well as the aspirator. In those cases where the lung has long been compressed by the fluid, is bound down, and has lost its resiliency, it may become necessary to use the aspirator. At any rate there is no time lost or harm done in first trying the syphon; if that does not act, the aspirator can be easily attached. The bottle form of aspirator should be discarded in favour of the more modern one where the suction is performed by force exerted by the hand, and is therefore much safer. When one has to perform paracentesis to relieve dangerous symptoms, the question arises as to how much of the fluid should be withdrawn. General experience has shown that relief of symptoms is obtained by withdrawing a portion only of the fluid in the pleural cavity. Two pints to two and a-half pints is generally sufficient, if all is taken away, remembering that the inflammation is still acute, there is great probability of the proceeding having to be repeated at an early date. When, on the other hand, the operation is performed to promote cure, a larger quantity may be withdrawn with benefit.

There is a class of simple pleural effusion which may be treated in a somewhat different manner. I refer to those small effusions which, in spite of ordinary treatment, persist and show no signs of being absorbed. These will very often quickly subside if a small exploring needle is inserted and a syringe full of fluid withdrawn. In some way or other the balance between excretion and absorption is turned in favour of the latter by this procedure.

We must now turn our attention to a consideration of pleural effusions, complicated with other diseased conditions of the lung, and there are many which to a great extent modify the treatment of effusion. The complication which is most important from the point of treatment is tuberculosis of the lungs. Phthisis is not infrequently present with pleural effusion, either on the same or the opposite side of the chest, in either case it makes the treatment of the effusion a very difficult matter. When it is on the side of the chest opposite to the effusion, the dyspnoea consequent upon the sound lung being, for the time, put out of work, is great. If the greater part of the lung on the opposite side is invaded with tuberculosis the patient stands in great danger, especially if the effusion is of rapid onset. The treatment in this case is clear. Prompt and efficient paracentesis must be done, and as often as the pleural cavity shows signs of filling up again, so the physician must be prepared to evacuate it. But even in this case it is not necessary to take away all the fluid, the relief is obtained by the abstraction of from two to three pints. In one case of this nature, where two-thirds of the right lung was invaded by tuberculosis, pleural effusion supervened on the left side. The dyspnoea was extreme, and when the pleural cavity was two-thirds full, a trocar was inserted, two and a-half pints were withdrawn and the relief was manifest. The operation had to be repeated on two subsequent occasions, but even-

tually the effusion ceased to collect, and a fair recovery was made.

Very different is the treatment of effusion when it occurs in the same side as the tuberculosis. Here the lung being largely out of use, so to speak, it does not so much matter if the rest of its breathing surface is destroyed. The distress is not great, and there is no need for such prompt treatment as when the pleural cavity on the opposite side is invaded. Indeed, my experience of such cases raises the question as to whether the effusion should be interfered with at all. I have found the presence of fluid in the pleural cavity exerts a very beneficial effect upon the tuberculous lung. In several cases the phthisis seemed to become quiet, the sweating and the temperature cease to give trouble, weight and appetite was gained, and except for dyspnoea the patients were in a better state than when free from effusion. On the other hand, when paracentesis has been performed, the tuberculosis has increased to an alarming extent, and in one case the patient who was suffering from chronic phthisis with no active symptoms before the paracentesis, rapidly became worse after the operation, and in a few months died of acute phthisis. It seems that the activity of the lung disease is in a large measure cut short by the pressure exerted by the effusion; possibly on account of the blood being driven from the lung. In support of this argument I may be permitted to read the notes of a case which I brought before the Society in 1895.

Therefore I would urge that when the effusion takes place on the same side as tuberculosis, no good, but on the contrary much harm, will result from interfering with it by paracentesis. When fibroid disease of the opposite lung occurs with pleural effusion, the case must be treated in precisely the same way as if phthisis were present in the opposite lung, namely, the physician must be prompt to relieve the distress as soon as it arises.

When pleural effusion arises complicated with cardiac affections, the treatment of course must be through the heart, not through the pleura. Occasionally, however, it may be necessary to withdraw the fluid from the chest. The same may also be said of pleural effusion complicated with kidney affections.

I do not know that the treatment of effusion complicated with new growths of the lung and pleura requires any special description.

It rarely happens that patients with emphysema and bronchitis are so unfortunate as to be subjected to an attack of pleural effusion, but when such is the case, a very small quantity of fluid will suffice to bring about distress to the breathing and the heart. Therefore, the treatment must be directed to removing the fluid as soon as these symptoms exhibit themselves. The same remarks also apply to the treatment of double pleural effusion.

I have not touched upon the subject of the treatment of pus in the pleura, because it seems to me that its treatment belongs to the domain of the surgeon. Still, I trust that although it has no place in this paper, yet it will receive due attention at the hands of the surgeons who will honour the paper by discussing it. Also I shall be glad to learn from them, what site they consider the best for inserting the trocar. For my own part, I prefer the back, as it has always seemed that the rib spaces are wider in that region. Another advantage is that the patient must sit up, and the least appearance of fainting can be at once noticed.

In conclusion, I feel that this paper is very imperfect; but the points raised appear to me to be of importance. Still I trust that after having given my views of the question, I may have the pleasure of being instructed by the views of those Fellows here to-night who take part in the discussion.

THE Eton boys, to the number of 300, are said to be "down" with influenza, and many well-known public men are among the victims.

NOTES ON A LAPAROTOMY FOR A RUPTURED OVARIAN CYSTOMA. (a)

By ALFRED SMITH, F.R.C.S.,

Professor of Midwifery in the Catholic University School of Medicine, Gynaecologist to St. Vincent's Hospital.

MR. PRESIDENT AND GENTLEMEN,—Ovarian cysts we know may spontaneously rupture into the peritoneal cavity or into some neighbouring organ. When they rupture into the peritoneal cavity the effect on the patient of course depends on the character of such a cyst and of its contents. A malignant cyst may rupture and be followed by dissemination of new growth in the abdomen. An innocent ovarian cyst generally produces but trifling symptoms. Each rupture is accompanied by sudden pain, profuse diuresis, lasting, it may be, for a couple of days, carries off the excess of fluid, and the tumour, altered in shape, gradually refills. There may be a true (a) acute rupture of an innocent ovarian cyst followed by fatal hæmorrhage and peritonitis. Death even may be so rapid that it seems due to septic intoxication from absorption of the fluid. In such cases there is generally a previous twisting of the pedicle followed by thrombosis of vessels, intracystic hæmorrhage and necrosis.

The following case will, I hope, be of interest to members of this Section as showing what grave symptoms and profound shock may follow spontaneous rupture of a common multilocular glandular cystoma. Dr. Leo Keegan, house physician to St. Vincent's Hospital, reports that he was called to see a patient on January 19th, about noon. She had been seized with a violent and sudden pain which she referred to the umbilical region. He found her in a collapsed condition, the abdomen was distended, the respiration was rapid, pulse 110, temperature 96° F. and she was bathed in a cold sweat. On careful examination he diagnosed an ovarian cyst, and concluded that it was a case of rupture and sent for me. While waiting my arrival he administered restoratives and kept a careful record of pulse and temperature. The patient recovered somewhat from the initial shock, but about 5.30 o'clock her temperature suddenly went up to 103.8° F and pulse 140; her condition became grave. On my arrival I determined to operate at once, and had the patient conveyed to the gynaecological theatre, St. Vincent's Hospital. I opened the abdomen, assisted by Mr. Paget Butler and Dr. Leo Keegan. I found a large transverse rent in the capsule and the peritoneal cavity filled with gelatinous cyst contents. There were numerous omental adhesions, and their separation was greatly hampered by the gluey fluid with which they were covered. Having separated the adhesions and tied pedicle I douched out with hot saline to remove as much of cyst fluid as possible without sponging. It was gratifying to find how the hot saline, temperature 101° F., seemed to liquefy the gelatinous fluid and facilitate its removal.

Condition of Patient after Operation.—A stimulating saline enema was given to the patient after operation. She spent a restless night from constant retching and thirst. In the morning the temperature fell to 100° F., pulse 132. During the day the pulse-rate increased to 140, temperature 100.6°. The abdomen became distended, and the colour of the vomit a dark green. It came up in mouthfuls without effort. Altogether the condition of the patient was very grave. I ordered the stomach to

be washed out with a weak boric solution. This gave temporary relief, and patient spent a somewhat better night. On seeing the patient on the morning of the 21st, nurse reported a return of the vomiting and much distension. I again ordered the stomach to be washed out and a large turpentine enema to be given, with good result. The pulse-rate and temperature fell, and the patient's recovery was uninterrupted.

The points of special interest are:—

1. The cause of the spontaneous rupture.
2. The explanation of the toxic symptoms before operation.
3. The treatment of the persistent vomiting after operation.

The Cause of the Spontaneous Rupture.—As a rule with large cysts their rupture is due either to traumatism, a blow upon the abdomen, a fall, the strain caused by vomiting, or to fatty degeneration caused by thrombosis. In my case the patient was lying in bed when the rupture occurred. She was a young woman, æt. 26, she was married one year and seven months, and she gave birth to a full term child eight months ago. She had a normal labour and puerperium. She noticed nothing unusual in her condition until three months after her confinement, she was then disturbed by a lump "falling about" from side to side, as she altered her position in the bed. Having consulted her doctor in November last he sent her up to Dublin for treatment. She was returned home, she says, as pregnant. The abdomen increased so much in size that she was sent up to me. I had not seen the patient until after the rupture occurred, but I am informed she was able to walk without distress or inconvenience. I am inclined to believe the rupture was due to tension from within acting on a fatty degenerated patch in the thin wall of the cyst. This accident, according to Pozzi (b) occurs most frequently in the case of gelatinous cysts such as was found in this case.

The Explanation of the Toxic Symptoms before Operation.—The fluid in glandular cysts is generally of fairly high specific gravity, 1010 to 1030. It contains much albumin and mucin, and broken-down cellular elements. The albumins are complicated, consisting of para-albumin and meta-albumin, the former being closely allied to mucin and the latter is designated by Hammarstein (c) as pseudo-mucin and by Pfannenstiel (d) as glyco-proteid. Now this pseudomucin is very abundant in cysts containing tough sticky fluid; it is a secretion, not a degeneration, and it does not occur in parovarian cysts. As toxic symptoms do not follow the rupture of ordinary parovarian cysts, it might be that the absorption of large quantities of this glyco-proteid would partially explain the toxæmia. Added to this the many broken-down cellular elements of various kinds which form part of the fluid would furnish ferments, the effect of which thrown into the circulation would give rise to toxic symptoms.

The Treatment of Persistent Vomiting.—This case I think illustrates the great advantage of washing out the stomach for the relief of persistent vomiting after operation. I do not now advocate the exhibition of gastric sedatives. Having washed out the stomach if the patient is much distended, a large stimulating turpentine enema is given to re-establish if possible the normal peristaltic action. The specimen presents no point of interest; it is an ordinary multilocular glandular ovarian cystoma.

THE THERAPEUTICS OF BAD-SALZSCHLIRF WATERS IN GOUT

AND THE URIC ACID DIATHESIS.

By F. ARTHUR PHILIPPI, M.D.,
Formerly Physician to the German Hospital, London.

As this health resort and its waters are very little known to English physicians, still less to the English public in general, although it has long been recognised by German medical men as a singularly effective remedy for gout (in all its forms), rheumatism, renal and biliary calculus, and a number of ailments included under the heading of impaired metabolism, it occurred to me that a few notes thereon might prove of interest to those members of the profession whose patients are likely to be benefited by a course of these baths or by the inhibition of the waters at home.

Salzschlirf is situated in Hesse Nassau, near the ancient cathedral town of Fulda, one of the oldest seats of Christianity in Germany, and the resting-place of St. Boniface (or, to call him by his secular name, Winifred), who came over from England to convert the unruly tribes of these districts. The nearest route from London is by way of Cologne and Giessen; a journey of some twenty-three hours, with a break at each of these two places. From Frankfurt on the Main it is three hours by rail, and from Cassel three and a half hours. From this it will be apparent that Salzschlirf occupies a very central position, from whence other points of interest are readily accessible. The country round about is hilly (the Spa itself having an altitude of 900 feet), though lying in a fairly extensive valley, sheltered by wooded heights from inclement winds on nearly all sides. Two streams joining just below the place produce a welcome amount of freshness in summer, and even when the days are at their hottest the nights are never oppressive. In general the climate may be described as fresh and bracing, though not over-stimulating, and well adapted for cases of nervous weakness and exhaustion.

The therapeutic resources comprise the "drinking-cure," baths, and massage. First in importance stands the St. Boniface spring, the water from which (bottled at the spring) is now being introduced into England, so that the treatment can be given a trial at the patient's own home. This well was sunk in the year 1838, and the analysis of the water executed at that time by Professor Fresenius gave very nearly the same results as one recently made in London. The water is alkaline and saline; by weight the chief ingredient is chloride of sodium (common salt), and in addition it contains carbonate of lime, iodide, and bromide of magnesium, and some minor additions, with a very considerable amount of free carbonic acid gas. In one respect, however, St. Boniface water is absolutely unique, and that is in the extraordinarily large amount of lithium which it contains. Of this mineral it possesses five, and even ten times as much as many better known "lithia waters." It is only due to obstacles of a mercantile nature that this spring has not hitherto become far more known to the world at large. Many medical authorities attach the greatest value to lithium in the treatment of gout and the uric acid diathesis in general, and this opinion receives much confirmation by the practical results obtained at Salzschlirf.

The other springs there are also not without value, notably the Tempelbrunnen, which is a ferruginous water, and of much use in cases of anæmia and chlorosis, and the Bitterwasserquelle, which acts powerfully on torpidity of the liver and digestive organs.

The baths comprise the effervescent saline ones and the *Moorbäder* or mud-baths. These latter are prepared from peat dug in the immediate neighbourhood, and though their exact composition is hard to define, they undoubtedly contain, in addition to the usual components, a large amount of iron in a more or less soluble state. These baths have been found very useful in the

treatment of the diseases above mentioned, and also in disorders peculiar to women.

Of the various other factors which make a Spa attractive, Salzschlirf offers less than it does of curative means. Those who go to a health resort merely to spend a few weeks in pleasant society, with abundant opportunities for amusement, would find more pleasure elsewhere. Still, the visitor here is not cast away in a desert. The Cur-house stands in very pretty and extensive grounds, with a large, roofed promenade in case of wet weather, and a tennis-court. Music is provided daily in the Cur-garden, and now and then is given a theatrical performance. Many of the German aristocracy, officers, and other persons of note are already regular visitors. Nevertheless, it should be clearly understood that Salzschlirf owes its increasing renown not to any extraneous allurements, but to the reality and excellence of the cures achieved there.

Clinical Records.

A CASE OF CHLOROMA. (a)

By G. H. MELVILLE DUNLOP, M.D., F.R.C.S.,
Physician to Royal Hospital for Sick Children, Edinburgh.

THE patient was a boy, æt. 9, admitted to the Sick Children's Hospital last October with the history that he had been in poor health for a year and was gradually becoming paler and weaker. Swelling of the face and protrusion of the eyes was noticed in August, and increasing deafness about the middle of September. The family and personal history was satisfactory. On admission, the boy was pale and apathetic; his whole body, except the face, was covered with small petechiæ, while large subcutaneous hæmorrhages were present along the vertebræ and outside the right knee. The internal organs were healthy; the teeth were carious and the gums swollen and in an unhealthy condition. There was considerable proptosis, especially of the left eye, and on examination the retinal veins were found dilated, and the discs swollen, while a few small hæmorrhages were present. The patient was very deaf, and the membrana tympani was greatly in-drawn in each ear. There was some anæmia, with a few nucleated red corpuscles, and about 20,000 leucocytes. On staining, it was found that the greater number of the leucocytes consisted of large lymphocytes, the condition being similar to that of lymphatic leucæmia. On October 27th a swelling which had a distinctly greenish tinge appeared on the hard palate, and a few days later similar greenish tumours developed in the temporal regions. The exophthalmos steadily increased, until at last the left eye could not be completely closed, while at the same time greenish tumours infiltrated the conjunctivæ and corneæ, and produced more or less blindness. Optic neuritis also was observed. The patient became progressively weaker, the anæmia increased, and the number of leucocytes went up to about 123,000 before death, the blood still retaining its lymphæmic character. The temperature began to rise, and death took place from asthenia. The case was extremely typical of the rare disease called chloroma, being characterised by progressive weakness, anæmia with lymphæmic condition of the blood, and the development of greenish tumours about the eyes and face. On post-mortem examination tumours of a light, grass green colour and firm consistence were found infiltrating many parts of the skeleton, the cranial bones and vertebræ being most affected. There were also numerous small nodules in both kidneys and in the wall of the heart, but the glands, thymus, spleen and other internal organs were spared. The tumour substance was especially abundant about the sutures between the cranial bones and in the pericranium. The temporal muscles were almost completely replaced by dense masses of greenish, gelatinous looking material about three-quarters of an inch in thickness. Chloroma had been first described by Allan Bevons in 1823, and since his day many cases had been reported and diverse opinions expressed as to its nature. He

(a) From notes read at last meeting of Edinburgh Medico-Chirurgical Society.

regarded it as a metastatic sarcoma of the periosteum, a view opposed by Recklinghausen on the ground that it did not contain the osteoid cells of an osteo-sarcoma. Recklinghausen described it as a lympho-sarcoma. The nature of the pigment was also a matter of dispute. According to some it was simply altered bile pigment, or a derivative of blood pigment, but more probably it was due to the presence in the cells of refractile granules (possibly fatty) or simply an exaggeration of the greenish tinge sometimes seen in the lymphoid tissues in leukaemia. Whatever its nature, the green colour disappeared rapidly on exposure to air and could not be preserved in formalin solutions. It seemed certain that the tumour originated primarily in the periosteum of the cranial bones, although some observers had thought that its source was to be found in the lachrymal glands. Notwithstanding the constant affection of the bones and pericranium, it was somewhat remarkable that the nervous system was never infiltrated. The kidneys, on the other hand, almost invariably showed metastases, but nodules in the heart, such as the writer's case showed, had not been previously described. The eye and ear were almost constantly affected, and deafness was a very common symptom in such cases. Microscopically, the tumours in this case showed the structure of a round celled sarcoma, with varying amount of intra-cellular supporting tissue. Chloroma was essentially a disease of youth, many of the cases having been in persons under fifteen, and, in the great majority of cases, males were the sufferers. All the more recent observations, where the blood had been carefully examined, tended to establish a close relationship between chloroma and leucocythæmia. Even when the number of the leucocytes was low, lymphæmia was almost always present. Probably the disease was not so uncommon as the scanty number of recorded cases seemed to favour, and when once the characteristic features—anaemia, with exophthalmos and progressive development of greenish tumours about the cranial bones—were recognised, the diagnosis could not be a matter of doubt or difficulty.

CASES OF LEUCOCYTHÆMIA PRESENTING PECULIAR FEATURES. (a)

By BYRON BRAMWELL, M.D., F.R.C.S.,

Physician to the Edinburgh Royal Infirmary.

1. A case of chloroma with lymphatic deposits in the skin, and a remarkable infiltration of the conjunctivæ, gums and larynx. The patient was a man, æt. 25, whose family and previous history was excellent. In October, 1900, he noticed that a lump appeared under the jaw, followed by a second similar one a week later. About the middle of January, 1901, numerous spots appeared on his chest, these were pale, about the size of a pea, and quite painless. In April he began to suffer from huskiness, obstruction in the nose, and swelling of the face and gums. When first seen his face was puffy, there was no exophthalmos, there was neither anaemia nor increase of the leucocytes, he was very deaf, his gums were enormously swollen, measuring $\frac{1}{2}$ in. in thickness, and the tonsils were much enlarged. The whole of the trunk was studded with tumours varying in size from a pea to a florin, and many of these had a faintly greenish tinge, while others were brownish. The conjunctivæ were swollen and fleshy looking from infiltration with new growth. The provisional diagnosis lay between melanotic sarcoma and some irregular type of leprosy, the latter, however, being soon discarded. On admission to hospital a more careful examination of the blood was undertaken, when it was found that although the red corpuscles numbered 4,480,000, and the leucocytes never exceeded 8,000, yet that 97 per cent. of the latter were small lymphocytes—that is, a condition of typical lymphæmia. One of the subcutaneous nodules removed for microscopic examination showed the structure of a lymphoma. The patient died, and towards the end of his life the swellings about the face assumed a green colour. Only a partial autopsy was permitted, and the cranial bones were not examined, but the epiglottis and neighbour-

ing parts showed an enormous infiltration with greenish tumour substance. The skin, glands, larynx, tonsils, gums and lymphoid tissues generally were similarly inflated, as also were the kidneys, spleen and the marrow of the ribs. This case he regarded despite the incomplete examination, as one of chloroma.

2. This was a case of *very acute lymphæmia*. The patient was a healthy man, æt. 33, who came up to hospital on a Saturday afternoon, complaining that for the past few days he had been deaf, and that the glands in his neck had begun to swell. As there seemed nothing urgent he was admitted without further examination, nor was the blood condition looked into. Next day he died, and on *post-mortem* examination some nodules were found in the skin of the back, the spleen and liver showed the appearances characteristic of lymphatic leukaemia; the epiglottis, larynx, and gums showed a state of matters exactly similar to what was found in the preceding case; the glands also were identical in showing a greenish discolouration and lymphoid infiltration.

3. This patient was a man who was sent to the surgical wards with the diagnosis of acute osteomyelitis some three weeks previous to his coming under the speaker's care. After admission, petechiæ developed, and he began to suffer from recurrent epistaxis, and became rapidly anæmic. On being transferred to the medical house he was found to be suffering from lymphatic leukaemia, the blood count being 3,000,000 red cells and 56,000 leucocytes, of which 97 per cent. were lymphocytes. He died of epistaxis very shortly after admission, and the autopsy confirmed the diagnosis of leukaemia. Dr. Bramwell pointed out that these three cases formed a series, the first being undoubtedly chloroma, and the third acute leukaemia, while the second was intermediate between them. The question of the relationship of leukaemia or lymphæmia to chloroma he could not regard as settled; he did not think that all cases showing the lymphæmic condition of the blood could be classed together, but probably as our knowledge increased we would be able to separate the cases into several independent groups.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEB. 14TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

MR. GILBERT BARLING

ON SEVENTY-FOUR CASES OF APPENDICITIS WITH LOCALISED SUPPURATION.

Of 140 cases of appendicitis operated upon in the acute stage seventy-four have been cases of localised suppuration in the right iliac fossa or immediately adjacent to it. In forty-six of these the abscess, though well shut off by adhesions, had not yet come forward so as to be adherent to the parietal peritoneum, and operation involved the opening of the general peritoneal cavity. In the remaining twenty-eight cases the abscesses had become adherent and were evacuated without opening the general cavity. The points to which attention is directed are:—1. The diagnosis of and the time at which pus should be evacuated; 2, the safety with which this can be done if the removal of the vermiform appendix is not insisted upon; 3, the rarity with which recurrence takes place if the appendix be not removed; 4, complications at the time of, or following operation; 5, certain risks to life which follow attacks of appendicitis apart from recurrence. The abscess should be attacked as soon as the diagnosis of suppuration is made, but it must be remembered that pus may be present in the presence of a normal temperature and pulse, though there may be other symptoms indicating it. Leucocytosis, though not pathognomonic, is decidedly valuable. In a series of twenty-one cases in which pus was present leucocytosis was only absent in two cases, and in every

(a) From notes read at last meeting of Edinburgh Medico-Chirurgical Society.

case examined where a high leucocyte count was found pus existed. The safety with which appendiceal abscesses may be treated if removal of the appendix is not insisted upon is shown by the small mortality in the cases under discussion. In the seventy-four cases there were two deaths. The appendix was only removed twenty-five times, and in forty-nine it was not removed. All but two of these patients in whom the appendix was not removed have been traced since, and of these two, both hospital patients, nothing can be learnt; of the other forty-seven patients only one has suffered from recurrence, a girl who had another attack within a few weeks of her operation, and who was subsequently operated upon successfully and the appendix removed. Complications were not numerous, and have been chiefly phlebitis and pleurisy and pneumonia.

Mr. F. C. WALLIS on the

TREATMENT OF INTRA-PERITONEAL ABSCESS OF THE APPENDIX ILLUSTRATED BY PAPERS.

This paper dealt with those cases of appendix abscess in which the abscess, although shut off by adhesions from the general peritoneal cavity, was in no way adherent to the abdominal parietes. It was therefore necessary to open the general peritoneal cavity before the abscess could be dealt with. In giving details of the operation, great importance was attached to the fact that all the cases referred to, except one, occurred in young people and that adhesions at this age were very frail and required delicate manipulation to prevent the pus under tension in the abscess sac from escaping uncontrolled into the general peritoneal cavity. To prevent this, Gamgee sponges were packed in a crescent around the affected area, and when possible the pus was gradually evacuated and sponged up as it appeared. When the amount and tension of the pus was too great for this to be done the patient was bodily tilted over to the right side and the escaping pus caught in a small bowl held underneath. When most of the pus had been evacuated the cavity was more freely opened and thoroughly cleansed. The appendix and its remains were then removed, and the cavity dusted with iodoform and packed with iodoform gauze. It was a matter of importance to keep the wound as dry as possible. The necessity for operating quite early after the primary attack in young people was strongly urged.

Mr. A. BARKER said he had seen several severe cases of recurrence after non-removal of the appendix. He referred to that of a lad, *et. 15*, who had five recurrences, several of which were accompanied by marked collapse. He thought that whenever possible the appendix ought to be removed. If this could not be done without adding materially to the danger of the operation it should be postponed until a quiet interval. He preferred warm saline solution for washing out the peritoneal cavity to solutions of powerful germicides, and the exit for such fluids should be quite free. He was in the habit of placing an aseptic gauze apron, which afforded more effectual drainage than did the tube. He dissented from Mr. Barling's views in regard to the site of the incision, he himself preferring to separate the muscular fibres sufficiently to obtain room to evacuate the abscess, a procedure which did not entail any great danger to the patient.

Mr. BERRY observed that while he was pathologist at St. Bartholomew's Hospital there was a certain surgeon who held that if one had not removed the appendix one had done very little for one's patient. As he carried this view into practice, he provided much material for him (the speaker) in the post mortem room. There were two schools of surgery, in one a small incision was made, and in the other a large. Of forty-one cases (during six years) with a small incision there were only two deaths, and in thirty-nine treated by various surgeons without regard to the adhesions there were thirty-two deaths. He had collected statistics in two London hospitals of the mortality of appendicitis. At St. Bartholomew's there had been in two years 242 cases, inclusive of those in the medical and in the surgical wards, and of this number thirty-nine died (one in eight). The mortality in the surgical wards alone

had been one in seven. At St. Mary's Hospital in 200 cases, medical and surgical, the mortality was twenty-five (one in eight), while in the surgical wards it was one in four (twenty-two deaths). He thought these figures represented approximately the mortality in the London hospitals. He thought that it was better not to be in too great a hurry to remove the appendix, and certainly not to remove it during the acute stage. At the Royal Free Hospital during the last five years, among self and colleagues, on the plan of waiting for adhesions to form and then opening, out of fifty-three cases forty-nine recovered and four died (one in thirteen). He asked whether in the diagnosis of suppuration the authors had ever remarked a very low temperature, an occurrence which he himself had noted.

Mr. WALLACE said that in looking through the reports between 1895 and 1901 he found eight cases of recurrent abscess—about 5 per cent. He thought much could be done in the direction of removing the appendix without infecting the general peritoneal cavity. He had himself removed the appendix in five cases through the abscess cavity, and all did well except one in whom the suppuration continued for a long time.

Mr. W. G. SPENCER was of opinion that the incision through the middle line instead of employing the iliac incision was responsible for a large share of the mortality alluded to by Mr. Berry. He was aware that a very high mortality had followed immediate removal of the appendix, indeed in the hands of one surgeon nineteen out of twenty, but that must have been by very bad luck. He regretted that Mr. Berry should advocate waiting when once pus had been diagnosed. He pointed out that there were no statistics for appendicitis, no two cases being alike. He challenged Mr. Berry's figures in respect of the comparative mortality between the medical and surgical cases. (Mr. BERRY denied that he had instituted any such comparison, and after some discussion the point was dropped.) Mr. Barling did not say in respect of the cases in which he had not removed the appendix whether the patients who survived were in good health. His own experience was that even if they did not relapse they did not enjoy good health. Of course there were patients who could not support a prolonged operation, and in whom, therefore it might not be advisable to remove the appendix at the same time.

Mr. KEETLEY pointed out that there was very little danger of infecting the peritoneal cavity if the pelvis and the parts around the site of the appendix were thoroughly packed with gauze, and if the intestines were kept out of the way by raising the pelvis or otherwise. The risk of perforating the intestine might be ignored in most cases if the surgeon took care to see what he was doing and promptly repaired any injury.

Mr. CHARTERS SYMONDS thought most surgeons would agree that it was better not to attempt the removal of the appendix unless the abscess was localised. He said they had not lost a patient in whom the appendix had not been disturbed. He discussed the comparative infrequency of adhesions in Mr. Barling's cases, and suggested that the reason was that that operator made his incision over the most prominent part of the swelling, where, in his own experience, there were often no adhesions. For this reason he advocated making the incision nearer the iliac spine. There were only two drawbacks to the non-removal of the appendix, viz., recurrence and prolonged suppuration. In two recurrences of his own the abscess had followed the line of least resistance, viz., the old track, so that there was not much danger to the individual. The existence of a sinus might necessitate the subsequent removal of the appendix, but later when things had quieted down. In looking over his cases he could discover no cause for regret that he had not forthwith removed the appendix. In point of fact, if one intervened early enough one could do what one liked. It was only when pus had formed that discrimination was required.

Sir THOMAS SMITH said he had always made his incision very low down, sometimes so low as to be below the reflexion of the peritoneum. If in such cases pus did

not come he left in a drain, and usually the pus worked its way through in due course. This was a plan not generally adopted, but which had given him satisfactory results.

Dr. CAYLEY said that judging from the figures he had collected the proportion of relapses was much less than 5 per cent., in fact, it worked out at about 1.5 per cent. He asked whether the authors had had any experience of a counter-opening in the lumbar region which, as a looker-on, had more than once appeared to him to be advantageous.

Mr. BARLING, in reply, said that on all his cases (about 300) the aggregate mortality was between 12 and 15 per cent. This included seventy-two cases of abscess with two deaths, relapsing cases with 1.5 per cent., and the cases of diffuse peritonitis or wide-spread suppuration, of which the mortality was, of course, much higher. He pointed out that the patient who got recurrences was he who had mild attacks. He had noted the low temperature in suppuration, but it generally rose in the evening. It was very significant in general peritonitis. He added that packing and secondary suture might be all very well, but for the patient it constituted a second operation and, moreover, it did not always fulfil their expectations. He much preferred to open right over the pus, wherever situated. As to the patients who had no recurrence after non-removal of the appendix their general health was usually perfect. He had used a counter-opening in the loin in a few cases.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD FEB. 5TH, 1902.

Dr. T. R. FRASER, President, in the Chair.

Dr. WM. STEWART showed a patient after compound dislocation of the ankle, with fracture of the neck of the astragalus and removal of the outer malleolus.

Dr. BYROM BRAMWELL showed cases of (1) aortic aneurysm simulating solid intra-thoracic growth, and (2) infantilism in a youth, *et. 19*.

Mr. CAIRD showed (1) a patient from whom eighty inches of gut were removed for tuberculous stricture and glandular implication, and (2) a case of inoperable rodent ulcer which had practically healed under treatment by the X-rays.

Dr. DAWSON TURNER showed (1) a patient suffering from rodent ulcer treated by Röntgen rays and ultra-violet light, and (2) a patient suffering from lupus treated by Röntgen rays and ultra-violet light. He also demonstrated an apparatus for generating ultra-violet light for the treatment of diseases of the skin. Physically, the ultra-violet rays produced were thrice as powerful as those of an ordinary arc lamp, while clinically they were thirty times as active. This was because the comparative absence of heat rays in the new apparatus enabled it to be brought very much closer to the skin than the ordinary Finzen light, and moreover rendered the water jacket unnecessary—a great advantage, as water was extremely impervious to ultra-violet rays. The substance which had proved most transparent to these rays was ordinary rock salt.

Mr. PUEVES showed Henle's screen for protecting the area of operation in breast and neck cases from infection due to vomiting of the patient, as well as from anaesthesia apparatus.

Dr. MELVILLE DUNLOP read a paper on "A Case of Chloroma, with Pathological Report and some Brief Notes on the Condition," which will be found under "Clinical Records."

Dr. BYROM BRAMWELL read notes of cases of Leucocythæmia, which will be found under "Clinical Records."

Dr. W. S. GREENFIELD said that the papers he had just heard had helped him to understand a case which he had had eighteen years ago, and which had always been a puzzle to him. The patient had had pigmented swellings over the body, exophthalmus, and enlargement of the gland. Dr. Bramwell (then pathologist to the infirmary) had performed the autopsy, and described the condition as multiple sarcoma.

Dr. GULLAND said that he regarded chloroma as identical with lymphatic leukaemia. His opinion also was in favour of lymphæmia being primarily of myogenous origin. His experience was that the number of lymphocytes present was accounted for by the extent of the implication of the marrow; thus, if the bones were little affected, one might have great enlargement of the liver and spleen but a low leucocyte count, and *vice versa*.

Dr. FRASER asked whether Lowit's parasite had been sought for, and

Dr. GULLAND replied that it had not, because it was only found in the spleno-medullary form of leucocythæmia, and further, he had great doubt whether it was anything more than an appearance due to faulty staining of the basophile granules.

Mr. C. W. CATHCART read a note "On a Method of Securing the Lingual Artery in Excision of the Tongue through the Mouth." It had seemed to him that when extensive operations for the removal of glands in the neck had to be undertaken conjointly with excision of the tongue, it would be advantageous not to require to make a separate incision for preliminary ligation of the lingual artery, but to tie it through the floor of the mouth. He, therefore, devised the following plan:—The tongue was split as in Whitehead's operation, and then, after dividing the geniohyoglossus, a director was passed behind the hyoglossus down to the hyoid bone, the muscle was then cut, when the fibres retracted spontaneously, and the artery could be found at the bottom of the wound.

The following card specimens were shown:—By Dr. Logan Turner: (1) Larynx and trachea from a case of diphtheria; (2) Two specimens of malignant stricture at the upper end of the œsophagus. By Professor Annandale: (1) Ruptured femoral artery and vein from crush of the thigh and fracture of the femur, with portions of femur removed at a second amputation in the same case, showing necrosis and ossifying granulations; (2) Branched renal calculus; (3) Epithelioma of nape of neck; (4) Vesical calculus, showing moulding from its position between lateral lobe of the prostate and bladder wall. By Mr. Caird: Tuberculous stricture of the intestine. By Drs. Gilson and Stewart Macdonald: (1) Spinal cord, showing pseudo-tubercles syphilitica; and (2) Hæmorrhage into cusps of pulmonary semilunar valves.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF OBSTETRICS.

MEETING AT THE ROYAL COLLEGE OF PHYSICIANS, ON FRIDAY, FEB. 7TH, 1902.

Dr. W. J. SMYLY in the Chair.

The following specimens were shown:—

1. The PRESIDENT: Uterus removed for fibro-myoma.
2. Dr. HORNE: Large fibro-myoma removed by myomectomy.
3. Dr. ALFRED SMITH: (a) An ovarian cystoma strangulated by twisting of the pedicle; (b) A solid ovarian tumour with pyosalpinx.
4. Dr. PUREFOY: (a) Concurrent uterine and tubal pregnancy; (b) Large ovarian multilocular cyst removed soon after parturition; (c) Two dermoid ovarian cysts removed from patient suffering from tuberculous peritonitis; (d) Small ovarian cyst.

Dr. ALFRED SMITH then read his paper—

NOTES ON A LAPAROTOMY FOR AN OVARIAN CYSTOMA, WHICH HAD RUPTURED SIX HOURS BEFORE REMOVAL, WITH SPECIMEN.

which will be found on page 187.

Dr. KIDD asked had any food been taken by the mouth before the operation, and, if so, what was its character?

Dr. W. J. SMYLY stated that he found rupture of ovarian cysts to be caused by tapping, particularly if the operation had been repeated. In one case, after laparotomy had been performed the contents of the cystoma had escaped into the peritoneal cavity, and so much time was occupied by wiping the matter from the

coils of intestines that the patient collapsed. He certainly preferred Dr. Smith's process of flushing out the cavity. Massage was also to be credited with causing the rupture of such tumours. He had seen the daily practice of massage diminish an ovarian cystoma to the vanishing point—the tumour had been ruptured and its contents rubbed out of the sac. Even gentle palpation has caused rupture. In the Adelaide Hospital, whilst very carefully palpating a tumour it burst, and at once he performed laparotomy. He found a malignant cystic tumour which he removed, and the patient recovered from the operation well, but some months after the disease recurred.

Dr. ALFRED SMITH looks on washing out the peritoneum as the rational method. Vomiting commenced from the moment of consciousness from the etherisation.

Dr. KIDD was then called on to read his paper,

NOTES ON A CASE OF INDUCTION OF LABOUR FOLLOWED BY ENUCLEATION OF FIBROID TUMOUR IN CERVIX.

Dr. Kidd had seen the patient when a little over four months pregnant, and thought it would be quite possible to deliver the patient without operating in case (1) that the tumour did not enlarge during further gestation; (2) that she came to Dublin again three months later; (3) that he was successful in inducing labour. Patient returned at the appointed time; having a large roomy pelvis and vagina, it was resolved to induce labour and attempt delivery. Labour was brought on by the introduction of a bougie between the membranes and the uterus. When the patient had been about thirty-four hours in labour the os was sufficiently dilated to enable two fingers to pass easily through it. The patient was then examined with the whole hand in the vagina under an anæsthetic; it was found that tumour invaded more tissue than was at first deemed possible, so that the cervix could not possibly dilate sufficiently. Enucleation was resolved upon. This was done the same day under chloroform, and cavity left by tumour partly stitched, then packed with iodoform gauze. About seven hours after the operation all uterine pains and contractions ceased, having lasted between forty and forty-eight hours and did not return for ten days, the os in the meantime closing very quickly, so that you could not introduce a finger. Owing to the packing of the cavity (where tumours had been) being left off too soon it filled again with blood clot and must have become infected by septic surroundings as the discharge from it became distinctly foetid; this occasioned renewed packing and washing out. About twelve hours after her baby was born the patient got a severe rigor, and temperature went up to 106° 4'; this came down gradually with appropriate treatment in two or three days, the uterus remaining well contracted and free from pain, the lochia remaining of good quantity and colour, and free from any taint. Moreover, milk was established in the breasts, and she suckled her child successfully. She went home to the country with her child well within a month of the birth of the child. Dr. Kidd thought he was very fortunate to secure such a good result, but in future would advise an examination under an anæsthetic in the first instance. He would never undertake the responsibility except in a properly equipped hospital, whether private or public, and lastly, he would attempt the enucleation before resorting to the induction of labour. Dr. Kidd referred to the statistics of many operators and observers, and concluded by quoting the improved statistics published by L. Thumin in the *Archiv. für Gynäk. Kol.*, Vol. lxxiv., No. 3, 1901, and referred to under the heading of "Current Literature" in the February number of the *Journal of Obstetrics and Gynecology of the British Empire*.

Dr. ALFRED SMITH said that Dr. Kidd is to be congratulated on the successful issue of his interesting case, and on the paper just read. He (Dr. Kidd) seemed to have gone through the whole literature of the subject. Leaving the general view to come to the point of interest in this special case, he thought Dr. Kidd would have had a better idea of what was to be done had he examined the patient under an anæsthetic. He makes it a rule to examine under an anæsthetic before deciding on

any course of action. He would argue against inducing labour. If easily enucleated, the labour might run to full term; if not, there was the Cæsarian section. When the tumour is situated at the upper portion of the lower segment, it is drawn up during the process of labour.

Dr. W. J. SMYLY said that tumours of the cervix are very uncommon. He remembers Dr. Kidd's uncle saying that he never saw one. When a tumour lies directly in front of the head he thinks it should be removed. "On and off" labours are not infrequent in cases of myoma. He has seen such an "on and off" labour continued for a fortnight.

Dr. KIDD, in reply, stated that he quite agreed that an examination prior to deciding on the operative treatment is the proper course, but the conditions of this case were exceptional. The patient had a large roomy pelvis with a big vagina, which in the previous confinement had been lacerated and never repaired. Last year he had a somewhat similar case, in which, on the advice of the President, he did not operate, and the woman went to full term and bore a healthy living child; she was warned that if she again became pregnant she should come into the hospital not later than the seventh or eighth month. When next heard of, the patient was in labour and had been so for seventy-two hours. He put on the forceps and delivered her—during the operation he found that the tumour had flattened out and the child's head successfully passed it without injury.

The meeting then terminated.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD FEB. 6TH, 1902.

MR. W. WATSON CHEYNE, F.R.C.S., in the Chair.

Dr. EWART exhibited a case of Scleroderma Associated with Raynaud's Disease in a Woman, and also read a paper on the same, giving the clinical history of the case and special reference to treatment. This will be found on page 181.

Dr. ALEXANDER MORISON asked whether, in view of the chronic malnutrition of the patient, and some evidence of a small thyroid gland, Dr. Ewart had employed the iodides or given the patient thyroid extract?

Dr. Barton and Dr. Sutherland also took part in discussion. Dr. EWART replied.

Dr. SIDNEY PHILLIPS read a short paper on RHEUMATISM AS A CAUSE OF EPISTAXIS IN CHILDREN.

Dr. Phillips read notes of several cases among many in which he had found epistaxis associated in children with effusion into one or more joints or with antecedent or succeeding rheumatism manifested by joint affections or by chorea. Dr. Phillips thought in cases of epistaxis in which no other cause for the latter was ascertainable, rheumatic affections were more commonly found than could be accounted for by mere coincidence. The rheumatic inflammation of a joint was often, as is commonly the case in children's rheumatism, quite unassociated with pain or other symptoms, and only found when sought for. Rendu, of Paris in the *Semaine Médicale* of June, 1884, had described epistaxis occurring in children who subsequently became the subjects of rheumatism, and Dr. Phillips thought it also occurred in children already rheumatic. Salicylates in toxic doses were known to produce epistaxis, but it was possible that in some of the cases of rheumatism under treatment by salicylates where epistaxis had occurred it was due to the disease and not to the drug. There was no antecedent improbability in epistaxis arising from rheumatism, since the latter was known to give rise to hemorrhage from other mucous surfaces and beneath the skin.

Dr. EWART was prepared to find that the association in question, had been overlooked simply for want of sufficient inquiry on the part of observers. The great frequency of epistaxis in childhood, which must be due to definite causes, hitherto imperfectly explained, must lead to its being not uncommon in children suffering from rheumatism, particularly as in this disease there

is a well-marked tendency to hæmolytic. There is, however, an additional factor besides increased fluidity of the blood which might have a greater share in this result—the mechanical factor of local congestion. In many cases of rheumatism, but especially in children, the first part to be influenced by the rheumatic affection is the tonsil. Any persisting chronic enlargement of the tonsil, which in itself may often account for an individual liability to epistaxis, is intensified by the rheumatic tonsillitis or sub-tonsillitis, and this might furnish a plausible explanation for an increased rate of occurrence of epistaxis as a direct result of rheumatism if on further investigation this important and interesting correlation should be confirmed.

Dr. LEONARD GUTHRIE thought that epistaxis alone was not sufficient evidence of purpura rheumatica, but referred to a case of acute rheumatism accompanied by epistaxis and subcutaneous hæmorrhages, which seemed to support Dr. Phillips's contentions. Tonsillitis was, however, very common in rheumatic children, and any acute febrile disturbance might determine a flow of blood to the tonsils and naso-pharynx and thus give rise to epistaxis. In his experience epistaxis was more frequently associated with migraine than with rheumatism in childhood.

Dr. ALEXANDER MORISON considered that any epistaxis in connection with rheumatism in the cases quoted by Dr. Sidney Phillips was probably due to mechanical causes; indeed, by a rheumatic affection of the pharyngeal tonsil.

Dr. Travers Smith, Cantley, Jaffe, Macevoy, and Sunderland took part in the discussion.

Dr. PHILLIPS replied.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD AT 20, HANOVER SQUARE ON
FRIDAY, FEB. 7TH, 1902.

The President, Mr. E. CRESSWELL BAKER in the Chair.

Mr. R. LAKE showed a case of tuberculosis of the larynx which had been previously under treatment in 1898. He had returned three weeks ago with the thyroid cartilage enormously thickened externally and rather hard. Internally there was a conical projection forward of the right ventricular band. The opinion of the Society was invited as to the nature of the thyroid.

Dr. DUNDAS GRANT considered it a case of tuberculous perichondritis and advised that the swelling should be opened and explored.

Mr. L. A. LAWRENCE showed a case of rhinorrhœa of some years' duration in a woman, æt. 36. There was deflection of the rupture to the right and polypoid degeneration of both middle turbinates. The rhinorrhœa was absent only when the patient had a cold. Both local and internal treatment had been adopted for some time, without avail.

Several members suggested that in this particular case the proper treatment would be to remove the polyp, and possibly the anterior end of the middle turbinates.

Mr. F. G. HARVEY showed a case of lupus nasi of many years' duration in a man.

Dr. H. LAMBERT LACK showed a case of partial membranous occlusion of the right posterior choana. There existed also a perforation of the cartilaginous septum.

The President and others pointed out that the membrane passed upwards from the Eustachian cushion, and was posterior to the choana, and considered it to be the result of cicatricial adhesions. The cause of the scarring was attributed either to congenital syphilis or to adenoids.

Dr. LAKE also showed a case of marked chronic œdema of the right arytenoid region in a man, æt. 40, who had been under anti-syphilitic remedies for three months without effect. The case was brought forward for diagnosis.

Mr. W. G. SPENCER excluded malignant disease, and concluded that the case was probably syphilitic.

Dr. St. CLAIR THOMSON suggested that it might eventually prove to be tuberculous.

Mr. ATWOOD THORNE showed a case of syphilitic ulceration of the palate occurring during a course of anti-syphilitic treatment. The patient was a man, æt. 23, who contracted syphilis in May, 1901, and had been continuously treated with mercury and iodide of potassium for eight months. His general health was very bad. In spite of treatment the uvula and part of the soft palate had been destroyed, and ulceration had occurred on the posterior wall of the pharynx. Opinion was divided as to whether it was syphilis alone or a mixed case of syphilis and tubercle. Mr. Thorne stated that there was distinct evidence of phthisis on physical examination, but no bacilli had been found in the sputum.

Dr. H. J. DAVIS showed a case of tertiary syphilis of the pharynx and larynx in which the voice was produced by means of the ventricular bands.

Dr. DAVIS also showed a case of laryngeal tuberculosis with granulation tissue between the cords.

Mr. E. B. WAGGETT showed a case of myeloma of the nose in a woman, æt. 30. There had been rapidly increasing nasal destruction since 1901, with frequent epistaxis. Rouge's operation was performed, and a large tumour removed. Healing within the nose was rapid, and the process was accompanied by so marked a diminution in the size of the cavity that Mr. Waggett asked whether this might be partly due to recurrence of the growth. It was thought that no definite signs of recurrence existed.

Dr. L. H. PEGLER showed a case of abeyance of nasal breathing in a female, æt. 23, in which the nasal passages were free. The patient also suffered from hysterical aphonic rhinalgia. The patient's speech, though aphonic, was "clipped"—a defect known as "rhinolalia clausa." Dr. Pegler thought that both the nasal breathing and resonance were shut off by a spasmodic contraction of the soft palate.

Dr. SCANES SPICER agreed with Dr. Pegler in this view.

Dr. PEGLER also showed a case of abeyance of nasal breathing in which the nasal passages were free, and the palate and fauces hyperæsthetic. In this case also the patient had difficulty in pronouncing her m's and n's. Dr. Pegler had closed the patient's mouth with his hand, in spite of which the patient refused to breathe until cyanosis set in, but finally she respired through the nose. Suspecting palatal spasm, he had fixed the palate by means of a tape passed through the nose and out of the mouth, and the patient had been thus enabled to breathe comfortably through the nose with closed mouth.

Dr. F. W. BENNETT reported that in the case he had shown at the last meeting he had explored the maxillary antra but had found no pus.

Mr. F. HUNTER TOD showed a case of œdema of the larynx with thickening of the palate, uvula, and fauces for diagnosis. There were no signs of pulmonary phthisis and no evidence of syphilis. Mr. Tod thought the diagnosis lay between tuberculous laryngitis and congenital syphilis. The opinions of the Society were divided between these two conditions.

Mr. WAGGETT showed a case of ethmoidal suppuration in a man complaining of excessive pain. The patient had been under treatment for many years, and though the intra-nasal condition was now satisfactory, pain persisted. Mr. Waggett suggested that the pain was of neurotic origin, and with this opinion several speakers agreed.

Dr. J. DUNDAS GRANT showed a case of subjective nasal obstruction which he considered due to anæsthesia of the nasal mucous membrane. Dr. Dundas Grant also showed some glass tubes specially constructed for the inhalation of medicinal powders for the patient's own use.

Munificent Gift to a Hospital.

UNDER the will of Mr. A. J. Dettmar the Committee of the Hospital for Epilepsy and Paralysis and other Diseases of the Nervous System, Regent's Park, has received the sum of £9,367 13s. 4d. for the new hospital now being built at Maida Vale. This gift will meet the contract for the first section of the building, but large sums are still required for furnishing and fitting.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 16th, 1902.

"SIAMESE TWINS."

THE event of the week was the separation of the little Indian girls, who were for a long time a curiosity of the Barnum Show. As one of them was threatened with tuberculous peritonitis it was resolved to separate them. For several days they were kept under observation and treatment in the hospital, and when the acute symptoms had abated the operation was performed, and up to the present the children are doing well. They were joined by a thick band running from the xiphoid cartilage to the umbilicus, which, by the way, was not duplicated. The band included a portion of the liver, as is usual in such cases. The skin when cut retracted rapidly, as if it were continually on the stretch, and beneath was a thick fibrous tissue, which, when severed, revealed the portion of hepatic substance. A double strong ligature was applied, and the operation was terminated by the thermo-cautery twenty minutes after the first incision. The children bore the operation well, and the amount of blood lost was insignificant. During the first twenty-four hours apprehensions were felt as to the final issue, not only on account of possible post-operative accidents, but also as regarded the moral effect on the children. However, as we have already stated, their condition is very satisfactory, and there is every reason to believe that, as an operation, it will be a complete success. As to the girl threatened with tuberculosis, hopes are entertained that with treatment that malady will be warded off.

Unfortunately the hardy operator, it has been said, laid himself open to the critics of the public Press by the publicity he thought well to give to the operation, and also by the fact that he accepted the offer of a cinematograph to take views of the different stages of the operation, and which will form in a few weeks one of the great attractions of the side shows.

Be that as it may, this operation can take rank with those for which the well-known audacity of French surgery has acquired universal admiration.

THE TREATMENT OF CHOREA.

According to Prof. Raymond, the best treatment consists in producing sleep by progressive doses of chloral with which bromide of potassium can be associated. During the daytime antipyrine in divided doses from thirty grains to a drachm daily gives very good results.

Dr. Paulesco considers that aspyrine is superior to antipyrine; it is given in the same doses, ten to twenty grains, three times a day.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 15th, 1902.

AT the Medical Society Hr. Kossman spoke on THE INDICATIONS FOR DESTRUCTION OF THE FŒTUS AND ITS JUSTIFICATION.

He first spoke of the judicial aspects of the question. Among both the Greeks and the Romans the practice of abortion was not an offence either legally or morally. Only about 500 years after the birth of Christ was there a change, and then it was carried so far as to

include all efforts to prevent conception. That the fœtus was actually living could not be determined with certainty until the stethoscope came into use. The Roman Catholic Church had up to quite recently maintained its old position of the absolute sacredness of fœtal life. In 1884 a Papal decree forbade the teaching of craniotomy, and in 1889 a second forbade the teaching of any method of treatment involving the death of the fœtus. In 1895 the artificial induction of abortion was permitted as, expressly declared, when it was the only means of saving the life of the mother.

Par. 218 and 220, German Penal Laws, placed no limit on the practice of the surgeon as regarded the induction of abortion, although commentators endeavour to show that the surgeon must act in the interests of the mother.

Ethically considered, the induction of abortion was only justifiable when it was probable that the fœtus would die before birth in consequence of the preceding death of the mother.

The killing of the fœtus during labour was a more difficult question to solve. The cases when the death of the mother must ensue from the continued life of the fœtus are very rare, and only occur in spontaneous delivery of cross or brow presentation with the knee backwards and when pulse and temperature showed the commencement of septic infection. In the majority of cases the question involved was whether, in order to maintain the existence of the fœtus, the mother must be submitted to a dangerous operation. In this case the value of the child's life must be weighed against that of the mother. According to statistics the value of an infant's life was that of a woman, *et. 23*. It was not shown by statistics that motherless children had a greater mortality than those with mothers. Against the objection that the mother might have further children, it might be urged that a woman in such danger at delivery would probably take measures to prevent further conception.

In the individual case other questions would come up for decision, such as the stage of pregnancy, the possibility of a syphilitic, hydrocephalic, deformed fœtus, &c. The state of health of the mother would also have to be considered. If, for instance, she were suffering from inoperable carcinoma one would be prepared to submit her to the ordeal of a Cæsarian section.

The statistics of Zweifel showed that the results of embryotomy as regarded maternal life were but 3 or 4 per cent. better than after Cæsarian section, and the statistics of the Johns Hopkins Hospital only showed a difference of 12 per cent. It was the speaker's hope that the statistics of Cæsarian section would improve.

It could not be questioned that the patient herself or her legal representative had the right to forbid the operation of Cæsarian section, and conversely no one could force the surgeon to the performance of embryotomy, when he was of opinion that it was unsuitable. If permission to perform Cæsarian section were withheld the surgeon must decline further responsibility and insist on another practitioner being called in and await his arrival, when he should give up the case.

Hr. Landau considered the speaker's limits of the justification of embryotomy to be too narrow. In the case of a pregnancy in the seventh or eighth months, for instance, or in a woman in an advanced stage of phthisis

one would not interrupt the pregnancy, but perhaps wait with a heavy heart until, in the agony, or immediately post-mortem, a Cæsarian section could be performed.

Hr. Dührssen said that according to the penal code prosecution and condemnation might follow the induction of abortion. A change of the law that would protect the surgeon was called for. As a matter of fact, there were obstetricians who completely rejected embryotomy. The results when Cæsarian section was performed in the hospitals could not be expected in general practice.

At the adjourned discussion, which was renewed on the 21st ult., Hr. Kaminer reminded the members of his paper read before the Society last year, on the

INDUCTION OF PREMATURE LABOUR IN PHTHISICAL WOMEN,

and held that, within the limits there laid down, there need be no fear of the criminal law. If the medical attendant had the consent of the mother he would be free from blame. Not only the probable death of the mother in consequence of her continued pregnancy, but the aggravation of the disease justified the induction of premature labour.

Hr. Freund agreed with the previous speaker. On the basis of his own experience he would advise, on being called in to any case of febrile abortion, always to look upon it as criminal, and to get an exact history before making an examination. Only by doing so could he protect himself in the event of the case ending fatally. Craniotomy, if properly carried out, was quite free from danger as regarded the mother, but Cæsarian section was not so. The obstetrician, without doubt, would be punishable who performed Cæsarian section without the express permission of the mother.

Hr. Czempin also believed that with conscientious adherence to the indications the penal code need not be feared. When it was apprehended that a stationary disease would get worse during the pregnancy or childbirth, the attendant would be perfectly justified in inducing abortion, provided he had the mother's consent. In the case of absolute contracted pelvis the attendant would also be justified in inducing abortion if the woman would not consent to Cæsarian section.

Hr. Friedemann did not believe that the getting over one or more bad confinements led women to prevent conception or to criminal abortion. He mentioned a number of striking cases in support of this view, and considered it impossible, especially in country practice, to avoid occasional craniotomy of the living child.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Feb. 15th, 1902.

TUBERCULOSIS, ITS ORIGIN AND NATURE.

At the "Gesellschaft" Weichselbaum gave an exhaustive review of our present knowledge of tubercle.

The earliest discovery of the tubercle bacillus was associated with opinions of a specific stock, in which the bacillus was to be found. Others contended that it was a constitutional anomaly that led to the germination of the microbe, while yet another party held that different noxa were necessary to produce the tuberculous state.

Koch has given a new impetus to these investigations by his apothegms: (a) The cause of tuberculosis is a specific spore bearing bacillus. It is acquired through the fine dust entering the lung and carrying the germ with it, tuberculosis is not proved unless the bacillus is found, the origin of tuberculosis required a peculiar disposition, and that tuberculosis is hereditary. These axioms have been altered, augmented, and diminished since their first promulgation, and still some part of them remain controversial.

For instance, the tubercle bacillus itself is not always met with as a simple bacillus, but often as fine branching club-shaped threads which many authors group as streptothrix or myco-bacterium, Hnepe and Fischer consider this form at this parasitic stage as a saprophyte. Besides these there are other "saurefester" bacilli which resemble the tuberculous so closely, both morphologically and physiologically, that it is difficult, if not impossible, to tell the one from the other.

Even the staining is no assistance for their differentiation as they take up the colour and resist acids and heat as the reputed virulent form. Such "saurefester" are to be found in the earth, or the grass of meadows, in the dung of cattle, as well as in milk and butter. The similarity does not end here. By injection into other animals fine miliary tubercles will be formed which will form quicker than the genuine bacillus at a summer temperature, and the tubercles never become caseous. One of these tumours was found on the body of a carp, having every particular common to the genuine tubercle bacillus except the rapid growth at a summer temperature.

Again, the tubercle bacilli found in fowls are not identical with those in the mammalia, as the tubercle of the fowl has no effect on the guinea-pig and *vice versa* Koch has recently assured us that the "perlsucht" of the non-mammalia is not identical with the tubercle of the mammalia. His origin of the spore formation being the cause may be entertained as an error, as the drying of the spores in combination with fatty substances have been considered the origin of the "saurefester."

According to Nageli, who found tubercle in 50 per cent. of the dead, we should expect a wider distribution of tubercle than has recently been affirmed that the germ is not ubiquitous, but is to be found in rooms where tuberculous patients have been lodged.

The production of tuberculosis depends largely on disposition. The mode of infecting is probably most frequently by the lung, although other ports of entrance have been proved by different authors. Baumgarten denies the germinative origin of tuberculosis altogether. He contends that tubercle bacillus is transmitted through the spermatozoon to the ovum, to which it imparted a sort of larval condition, and during the first year of life the bacillus again becomes active and selects the apex of the lung at a later period.

Klebs and Aufrecht believe that the alimentary tract is the port of invasion; the latter fixing on the tonsils as the particular point from which the bacillus passes to the lymph ducts, and subsequently to the cervical and mediastinal glands, from which it travels to the apex of the lung by the bloodvessels. By this theory he accounts for vascular tuberculosis and thrombi. The selection of the apex is more from disposition than selection, as the circulation is slower, and thus allows the germ to linger,

where it finally takes root. Besides the tonsils the mesentery is pointed to as another port of entrance.

Ribbert supports the opinion of inhaling the bacilli into the lung, thence passing to the bronchial glands, and, finally, entering the perivascular lymph spaces.

Weichselbaum is sceptic about Baumgarten's theory, as the tubercle bacillus is rarely to be found in the urogenital system. Again in the new-born child the bacillus is rarely to be found before the first year and increasing up to the sixtieth. Experiments on animals also prove the placenta void of the bacilli.

Klebs thinks the infection is carried into the body by the ingesta as well as the air passages. By the ingesta is still controversial, as deer, sheep, goats, and asses have all proved negative to these tests. The flesh and milk when infected with "perlsucht" have also failed to produce tuberculosis. It has been proved also that the germ may be carried through different generations without showing any virulent effect. Racial influence has also much to do in the modification. Karlinski found the Bosnian deers very resistant to "perlsucht," while men were very sensitive to it. He could only inject ten out of twenty-five deer with human tuberculosis. The reverse is not proved yet, although the hypotheses are many.

The Operating Theatres.

GREAT NORTHERN HOSPITAL.

OPERATION FOR DISEASE OF THE PANCREAS INVOLVING THE STOMACH.—Mr. PRYTON BEALE operated on a man, *æt.* about 50, whose history was as follows: He had been admitted about three months before with intense pain in the epigastric region following the ingestion of food; he gave an account of hæmatemesis some weeks previously; he then remained in the hospital for about a week, and as the pain subsided he decided not to undergo an exploratory operation and was accordingly discharged. About three weeks afterwards he returned with increased pain and considerable emaciation. The following operation was performed: The stomach was exposed in the ordinary way by an incision through the linea alba and was found to be adherent to a large mass along its greater curvature for a distance of about four inches. This mass was found to be a growth involving the pancreas, but as some healthy pancreatic gland tissue was seen over it, it was decided to separate the mass from the stomach, but not attempt to excise it. This separation was effected without much difficulty, but so adherent was the stomach to the mass that a rent of about three inches in length in the viscus occurred. The edges of this rent were trimmed with scissors and then brought together by interrupted catgut sutures placed about a quarter of an inch apart. The sutures were of thick catgut and were inserted so as to include everything except the mucous membrane. Several large vessels in the pancreatic mass were ligatured, and the external wound closed and dressed without the insertion of a drainage tube. During the operation all ordinary care was taken to prevent any contents of the stomach passing into the peritoneal cavity, but more importance was attached to rapid performance of the operation than to protecting the peritoneal cavity. Mr. Beale pointed out that the pancreatic mass contained a number of caseous nodules,

and appeared to be a tuberculous affection of the pancreas itself, but this, he said, would probably be cleared up, for if the patient continued to emaciate he should attempt to remove the whole of it. An operation of this sort, he remarked, like all those involving suturing of any part of the digestive tract with the removal of a growth adherent to the same, should, if possible, be always undertaken at two sittings so as to reduce the amount of shock which more commonly than escape of contents of the stomach was the usual cause of death. The peritoneum, he said, was obviously capable of resenting infection, as was evidenced by cases of acute suppurative peritonitis, which in the present day frequently recover. He thought the great point seemed to be to perform the operation as quickly as possible, and, in so doing, to contaminate the peritoneum as little as possible. In a case like the one on which he had just operated, whatever care the surgeon took it was impossible for him to be certain that no stomach contents entered the cavity of the abdomen, and to introduce sutures into a rent three inches long in such a way as to make a watertight join meant introducing several rows of sutures very close together, which must take up considerable time. From what he had seen he had come to the conclusion that it was these prolonged operations which caused the patient to suffer so greatly from shock, and which proved in so many cases fatal.

A fortnight after operation the patient was getting on extremely well, and had suffered practically no pain. If he continued to progress favourably for another week it was proposed to attempt the removal of the pancreatic growth.

OPERATION FOR INTESTINAL OBSTRUCTION FOUND TO BE CAUSED BY RETRO-PERITONEAL SARCOMA.—The same surgeon operated on a healthy-looking man, *æt.* 35, who had been admitted with the following history: He had been perfectly well until three days previously, when, whilst standing, he felt a sudden and severe abdominal pain about two inches below the level of the umbilicus; at the same time he felt faint, and was carried home and put to bed. The pain increased and his bowels could not be opened either by purgatives or enemata. A median abdominal incision of about five inches in length was made, with the umbilicus as its centre. The small intestine was found collapsed and tonically contracted, and along its peritoneal attachment throughout the whole length there was a band of recent hæmorrhage, about a quarter of an inch wide (it was judged to be recent by its intensely bright red colour); there was a good deal of thickening of and hæmorrhage into the mesentery, and along the whole of its peritoneal attachment there was a large hæmorrhagic soft mass. A piece of this was removed for microscopical examination. A large vein was found to be bleeding freely, so a pair of Spencer Wells' forceps was put upon it and left. A considerable amount of blood-stained fluid was then washed out of the peritoneal cavity and the external wound closed, the handle of the forceps being left outside and a gauze plug inserted close by. Mr. Beale said that the diagnosis in a case like this was quite impossible because there was so much distension of the abdomen (chiefly due to large intestine) and so much pain that nothing could be felt within; even under an anæsthetic it was impossible to make out any tumour. The sudden onset of the pain was also quite misleading. It was

noticeable, he said, that in such cases the mere performance of an exploratory laparotomy sometimes relieved the symptoms of acute obstruction which had resisted all other means of treatment. There was, of course, no possibility of removing the growth.

The same evening eight grains of calomel were administered by the mouth, and this caused a good action of the bowels, the motion containing some blood. A portion of the growth was examined and was found to be a round-celled sarcoma, with numerous recent hæmorrhages in it. The wound was dressed the next day and the forceps removed, and a week later the patient was apparently going on very well, his bowels being relieved regularly.

THE DIAGNOSIS AND PROGNOSIS OF PHTHISIS.

In the minds of many medical men, and especially those who have but infrequent opportunities of examining patients suffering from pulmonary disease in the early stages, the diagnosis of pulmonary tuberculosis is probably too frequently postponed till the appearance of tubercle bacilli in the sputum. There is a danger that students, too, who are often charmed by the simplicity with which the diagnosis can be made when the bacilli are found in the sputum, may be led to take less pains to perfect themselves in the practice of the physical examination of the chest. As the public become more alive to the risk of infection from "consumptive" patients, so will the practice of the physician become more embarrassing. The public do not, nor can they be expected to readily understand that though the micro-organism be undoubtedly present in the tissues of a tuberculous patient, yet it may not be possible to find it in the sputum, even after many careful examinations. After their discovery be made, very little reliance can be placed on the number found in subsequent examinations in forming an opinion as to the condition of the patient. Because tubercle bacilli are found on the first bacteriological examination of the sputum, this does not

prove that the patient's condition is any worse nor indeed, need it be as serious as that of a patient in whose sputum none can be found even after repeated efforts have been made. Many medical men seem to think that, because the sounds heard over the chest are "dry" that therefore the tuberculous process is less active than when they were "moist" regardless of the fact that the "moist" character is largely due to the presence of catarrhal secretion in the bronchial tubes, which need not necessarily be directly due to the tuberculous process even in an admittedly "consumptive" patient. In considering the question of prognosis too great stress is laid by many on some one particular sign; this is most frequently the weight of the patient. They seem to think if he grow fat he is necessarily doing well. It is not good for any man to be "fat." These subjects are seldom long-lived. Dr. David Lawson (*Scottish Medical and Surgical Journal*, January) has lately pointed out in an able and convincing manner that though a persistently normal temperature and pulse-rate, and an increasing weight almost invariably indicate a favourable course, yet no one of these signs alone is incompatible with a downward course. Dr. Lawson refers to the "tuberculous temperature," "the temperature of the tuberculous person," &c., and in the connection in which he uses these expressions he is in the main, no doubt, correct, but it is important to remember that in cases of tuberculosis of the lungs we have, unfortunately, only too frequently to deal with the effects of a double infection. In cases in which the temperature of the patient is very high it is probably most often due to poisoning by septic micro-organisms. In the lungs and intestines septic infection of tuberculous foci and *débris* is less easily guarded against, and takes place earlier than in other places, and in them the effects are usually most pronounced.

OIDIOMYCOSIS OF THE SKIN.

DR. HOWARD T. RICKETTS, in the last number of the *Boston Journal of Medical Research*, has published a most valuable monograph on those parasites of the skin which are considered to belong to the classes of blastomycetes and saccharomycetes. He gives a most careful study of the pathogenic properties of the oidium group, and affords a critical analysis of so-called blastomycetic injections in man. In the clinical cases detailed there is essentially a uniform clinical history, the following being the chief features: An incipient papule which becomes pustular, yielding a glairy, somewhat tenacious pus. Gradual extension of the ulcerating surface, which is soon covered with coarse, soft and friable papillæ, and is surrounded by a reddened areola in which many minute abscesses are visible. Cicatricial healing in the oldest portions of the lesion as the border advances. A variable amount of pain, depending on the site involved, upon a temporary increase or decrease of the virulence of the specific infection, and the amount of secondary infection present.

The absence of lymphatic glandular involvement in a great majority of cases. (It seems probable, however, when generalised infection occurs, that it may take place through the medium of the lymphatic system.) The protracted and progressive course of the disease which may extend over ten or twelve years, and in the face may cause great cicatricial deformity. Periods of rapid extension interrupted by periods of relative quietude. The tendency of the scar to eventually approach the appearance of normal skin. The upper extremities (hand and fore-arm) and the face are most frequently attacked, although no portion of the skin is proof against invasion. Extension to mucous surfaces does not occur readily. Absence of general toxic disturbances, attributable to the local infection. Dr. Ricketts' conclusions will be of much interest to pathologists and especially serviceable to dermatologists. He holds that the so-called protozoic disease of Posadas, Wernicke, and others; Busse's and Curtis' saccharomycosis hominis, and Gilchrist's blastomycotic dermatitis are various manifestations of the same disease. The condition in the skin possesses constant clinical and histological characteristics, which separate it positively from all other skin diseases, particularly verrucous tuberculosis, carcinoma and syphilis. The organisms isolated from various cases differ in minor respects among themselves, but are so closely related morphologically and biologically as to justify their inclusion in a common genus, *Oidium*; they are thus analogous in a pathogenic sense to the fungi which cause actinomycosis, and to those causing trichophytosis. The variations among the organisms allow the recognition of three morphological types: blastomycetoid, or yeast-like; oidium-like, and hyphomycetoid. There are two histological forms of the disease in the skin, the eosinophilous and the non-eosinophilous, the former being associated with the mould type of the organism. He further suggests that oidiomycosis is an appropriate term for the conditions caused by the organisms, and oidiomycosis cutis for the disease as it occurs in the skin. Aside from the infections considered in Dr. Ricketts' communication, certain cases which have been described in the literature from time to time indicate that oidium-like organisms may cause other severe pathological conditions in man, especially when involving the lungs. The paper is beautifully illustrated and furnished with a very complete bibliography.

MODERN LIFE AND LONGEVITY.

THE ideal of the sanitarian no less than of the enlightened politician who has the interests of the community at heart would be to place a reasonable chance of attaining old age within the reach of all mankind. As things at present stand the average life is probably less than half the length it would be under favourable circumstances. The contributory factors to old age are manifold, and all of them require consideration in order to arrive at any sound

conclusions regarding the influence of modern social life upon longevity. One of the most important general observations of the kind was advanced by the late Sir George Humphry, who contributed an exhaustive monograph to the literature of the subject. We refer to his statement that the hereditary influence is strongly marked in the case of persons who reach old age. In some instances the soundness of an inherited constitution has enabled the fortunate owner to reach a centenarian age in spite of poor circumstances and even of serious attacks of illness. At the same time the general proposition which adds healthy occupation and easy circumstances to the contributory list will be readily accepted. Country life is more favourable than that of towns, although the latter can boast a fair number of centenarians in relation to population. The influence of occupation upon length of life has been exhaustively investigated both by the life insurance actuaries and by the student of vital statistics from the standpoint of preventive medicine. Indeed, few more terrible pictures could awaken the conscience of a community than that of the lives sacrificed annually at the shrine of the industrial Moloch. The last generation has witnessed the great improvements in the lot of the working classes which are embodied mainly in Factory Acts. In many trades a man is old at forty. A comparison of the mortality returns of counties where mines and manufacturing abound, as in Lancashire and Cheshire, with counties that are mainly agricultural will show emphatically the enormous relative waste of urban and industrial as against rural and agricultural life. At the same time the gradual development of preventive medicine, which makes life safer in a variety of ways, has led to the preservation of a multitude of lives that would otherwise have perished. Some authorities, notably Sir Crichton Browne, have contended that this saving of life does not materially increase the actual number of old persons among the population. From *a priori* grounds it is difficult to avoid the surmise that the number of individuals arriving at sixty-five, which has been adopted as the official definition of "old age," must sooner or later be very largely augmented. It has been attempted to prove the contrary by statistics, but a critical examination at once reveals various sources of fallacy in such conclusions. For instance, the results of improved preventive administration are being brought about in many cases in the most gradual manner. Many vital points of the subject have been only recently and partially handled by the Legislature, as in dealing with dangerous trades and laundries and other details of factory legislation. No serious attempt has yet been made to grapple with measles and whooping-cough and summer diarrhoea, which are the most deadly of the zymotic diseases. The great Board School system, again, is not yet brought under any system of efficient medical control, a condition that is absolutely essential in preventing the spread of infection among a congregation of children at

school age. The element of time is needed to bring all great reforms to perfection. That same test of the lapse of a sufficient period of years is needed before one can form a satisfactory opinion as to whether the great and acknowledged increase of young and middle-aged lives has or has not added materially to the number of the aged inhabitants of the community. Clearly the results, if we take a limited period, say, of fifteen years, may be upset by some comparatively simple accident, as for instance the influenza epidemic which has settled down in the United Kingdom from about the time mentioned, and which is notoriously fatal among aged persons. On these grounds, with all due respect to the views of so distinguished an authority as Sir Crichton Browne, we venture to think that judgment will have to be suspended for a generation or two before any trustworthy general conclusion can be formed upon the point. The stress and hurry of modern life certainly do not appear on the face of things to be conducive to old age. The changes that lead to senile death are usually those of atrophy, which is simply in most cases a sign of earlier stress and storm. On the other hand, we find everywhere and in all ranks of society, from the highest to the lowest, an encouraging proportion of centenarians, many of whom retain their peculiarities unimpaired, and give testimony to the marvellous perfection of the bodies with which Nature has endowed mankind as the result of countless centuries of the stern but ever upward process of evolution.

Notes on Current Topics.

The Epidemic of Small-pox.

THE epidemic of small-pox continues to extend in London, and, as we anticipated, fresh centres of infection therefrom are being almost daily reported from the provinces. The serious nature of the situation is in that way greatly enhanced, and the moral of Mr. Balfour's foolish Vaccination Act is likely to be brought home to conscientious upholders as well as to conscientious objectors throughout the kingdom. Cardiff has been invaded during the week by a marine fireman, who had tramped from Liverpool to London, where for a fortnight he tried to get work, but being unsuccessful he went to Cardiff; shortly afterwards he developed small-pox. The Medical Officer of Cardiff has issued handbills stating that in the Gloucester epidemic of 1896 only twenty-six vaccinated children under ten years of age took small-pox, and only one of them died; whereas of 680 unvaccinated children who took the disease 279 died. An outbreak of small-pox in Cardiff, as an important shipping centre of South Wales, would be most disastrous. The *Times* last week contained a sound, practical suggestion from a well-known medical officer of health, to the effect that a great inducement to working persons would be held out by offering them money compensation for the two or three days during which they were incapacitated by the effects of vaccination. Among recently invaded

towns are Exeter, Oxford, Portsmouth, Dewsbury, Barnsley, Birmingham, Peterborough, and Dublin, while a score of towns have been invaded in Kent, Surrey, and counties bordering on Middlesex, Essex has suffered severely, no less than 454 cases having been notified therein since August, 1901. In South Wales, Glamorganshire has been invaded, and fresh cases have been reported from Swansea, Ystalyfera (seventeen cases), and Merthyr. A mild but sustained epidemic has been running in Glasgow for several months past. At the Metropolitan Asylums Board meeting of February 9th it was stated that up to date there had been 3,000 cases of small-pox in the Metropolis since August last with 560 deaths. In the face of these figures it seems absurd on the part of a special correspondent of the *Standard* to speculate on what steps should be taken "if the epidemic became really serious." The total number under treatment up to midnight, Sunday, was 1,193; 71 fresh cases were notified on Monday, February 17th.

Public-houses and Small-pox.

Now and then a local authority in some part of the United Kingdom illuminates the mists of popular prejudice and apathy by some act of administrative brilliancy. That has recently happened with the Urban District Council of Barnet on the occasion of the closing of a public-house in the district by the medical officer of health. The reason of the closure was that a militiaman billeted with the publican had contracted small-pox. So far all is plain sailing, but the special wisdom of the Council was shown in the subsequent step in undertaking to compensate the landlord liberally for his loss of business. This principle, which was sanctioned by the district justices, is thoroughly sound, and its more general application would undoubtedly do much to check the spread of infectious diseases. A little consideration will show the truth of that proposition. In the first place, given a tradesman's shop or a public house, there can hardly be a centre better suited for the wholesale spread of an infectious disorder around its immediate sphere of activity. No more striking instance of the kind could be cited than the scarlet fever epidemics that sometimes follow the invasion of a dairyman's household by that particular disorder. Yet the compulsory shutting up of a business inflicts a great hardship on the small and the struggling tradesman. What is the best public policy to pursue under such circumstances? To our mind the answer to that question lies in the application of some liberal scale of general compensation such as that adopted in the particular case of the publican at Barnet. The danger is from concealment of infectious maladies, and ruin in business is clearly a strong incentive to secrecy.

Epilepsy and Crime.

A RECENT murder trial has brought forward once again into fierce light the question of epileptic responsibility. The facts are simple. A young man had been assistant, since the age of fifteen, in a fish-

monger's shop. He was addicted to drinking, and a week before Christmas he was dismissed, apparently for having threatened the foreman with a knife, under the influence of alcoholic excitement. A few days later, after having spent the day with a friend "visiting many public-houses," he rushed away in a frantic mood to the fishmonger's shop, where he stabbed the unfortunate foreman to the heart with a fish-knife. At the trial it was stated that since 1901 the prisoner had been irritable, sullen, and forgetful, and had suffered more frequently from the epileptic fits to which he was subject. The defence was that the crime was committed while accused was under the influence of epileptic mania. The judge, Mr. Justice Bigham, treated the defence as lawyers are wont to treat the medical aspects of moral sanity. In passing sentence of death, he said he personally had no doubt that the prisoner knew he was killing the man, and that he intended to do it and knew he was committing a wrong and wicked act. For all that, the learned judge must surely admit that a family history of insanity, taken in combination with a personal history of drink, epilepsy, moroseness, and murder without a reasonable makeweight, so to speak, of motive or incentive, is suggestive of insanity. At any rate, we should feel, for our own part, that the ends of an ideal justice might possibly have been attained with more certainty had the prisoner's case been submitted to the impartial judgment of a small body of lunacy experts.

The After Care of Lunatics.

At the recent annual meeting of the After-Care Association for poor persons discharged recovered from asylums for the insane, it was stated that about 7,000 patients are discharged every year from asylums in this country. Such a fact clearly indicates the need for organised means whereby help may if possible be rendered in preventing a recurrence of the mental derangement. The After-Care Association during the past year has dealt with 214 cases, 139 being women and 75 men. Many had been boarded out in cottages in the country, and others had been assisted by grants of money, clothing, and promises of situations.

Medical Practice in the Transvaal.

UNDER a recent proclamation a Medical Board has been constituted to regulate the practice of medicine in the Transvaal. Provision is made for the admission of all duly qualified persons as physicians, surgeons, and dentists, but it is expressly stipulated that the holders of such diplomas shall only be eligible for registration provided that they are thereby entitled to practise in the respective capacity in the country in which they have been granted, thus excluding diplomas like that of the University of Brussels, which confers no legal status in that country on its holders. An even more commendable proviso is that such diplomas will not be recognised and admitted unless by the laws of the country in which they have been issued. British subjects legally qualified to practise in Great

Britain are afforded privileges equivalent to those granted by licence under this proclamation. Some of the criticisms levelled at the purport of the proclamation see in it an occult attempt to deprive Dutchmen and Germans of the right to practise medicine and dentistry in the colony, but as a matter of fact, it excludes the diplomates of all European countries except Italy, while American practitioners will presumably be entitled to the franchise. We repudiate any leanings in the direction of protection in such matters, but if we wish to impress upon foreign governments the desirability of arriving at some understanding as to reciprocity of medical practice some such restrictions cannot well be avoided.

Extra-Uterine Triplets.

It is very uncommon to be able to find the embryo in a case of extra-uterine pregnancy, as it is frequently absorbed prior to operation. How much more rare, then, are cases in which more than one foetus has been found. Yet in a recent number of *American Medicine*, Dr. Wilmer Krusen, Instructor of Gynæcology at Jefferson Medical College, Philadelphia, records an interesting case of triple ectopic gestation in which all the embryos were found. The patient, aged 34, had for some time suffered from symptoms of pelvic inflammation, and had had five miscarriages. When first seen, on June 12th, she gave a history of amenorrhœa for six weeks, and said that two days before, while in the street, she was seized with acute abdominal pain and faintness. She partially recovered from this, but later on the symptoms becoming more marked and fever setting in, on June 19th Dr. Krusen was called in, and diagnosed ruptured ectopic gestation with intra-peritoneal hæmatocœle. Immediate operation was advised, but not undertaken till the 21st. When the abdomen was opened it was found full of dark blood-clot and three perfectly formed foetuses were removed. The gestation had occurred in the right tube, and the rupture did not involve the cornu of the uterus. The left tube was inflamed, but intact. Unfortunately the patient died three days after the operation of peritonitis. The case is recorded as one of actual unilateral triple tubal gestation, the interstitial structure of the uterus being uninvolved.

Insufficient Instruction in Midwifery.

FOR the student of medicine who aims at ultimately becoming a general practitioner in the country there is nothing more important than a good practical knowledge of midwifery. This fact is so generally recognised that it is with considerable surprise we read the following statement in Mr. R. Milne Murray's paper on the Teaching of Midwifery, published in the January issue of the *Edinburgh Medical Journal*.—"It comes to this then, that the vast majority of Edinburgh students (and so far as I can gather it is much the same in most other places) leave Edinburgh without any experience in the proper conduct of labour, normal or abnormal. Very few of them have seen

an ordinary labour conducted from start to finish by one competent to demonstrate how little is required on the part of the accoucheur in the management of an ordinary labour; nor have they been shown with that scrupulous care that little has to be done. Not one in ten has seen the forceps applied, and fewer still have seen any of the other obstetric manipulations or operations. This, then, is the best that Edinburgh can offer them." We are glad to say that such a statement could not be made of the Dublin school, and trust sincerely that matters will soon be mended in Edinburgh. It is interesting to ask, in this connection, how many cases is it necessary for a student to personally conduct before he is admitted to his final examination in midwifery? We believe the number is three, but speak subject to correction.

The Midwives Bill.

THE new Midwives Bill was issued in the course of last week. The principal changes are (1) a system of notification of practice to the local authority is substituted for the annual licence of the last Bill, following the precedent of the Infant Life Protection Act; (2) the duty of forming the Central Midwives Board is laid on the Lord President of the Council instead of on the General Medical Council; the constitution of the Board will remain the same; (3) the rules regulating the practice of midwives are to be formulated by the Privy Council, and submitted for consideration and report to the General Medical Council, but the Privy Council will finally decide upon their provisions; (4) the practice of uncertificated women is not to be made illegal, although the use of the title "midwife" is to be forbidden; in this the Bill is in accordance with the medical Acts. Two important clauses of last year's Bill, *i.e.*, (2) and (10) have thus been materially modified as to alter the whole character of the Bill, which is so far rendered less satisfactory to some of its former promoters. Sir J. Tuke has, we learn, withdrawn his name from the back of the Bill, as he does not approve of all the changes which have been made.

Small-pox in Dublin.

A CASE of small-pox occurred in Dublin last week, the patient being a sailor who had recently come from Glasgow. He was at once removed to Cork Street Fever Hospital, and from there to the temporary small-pox hospital at Beneavin. The inhabitants of the house in which he had lodged have been placed under strict supervision, and so far two more cases have been recorded. It is satisfactory to learn that the Corporation have acted on the recommendation of the Dublin Sanitary Association, and have placed chicken-pox on the list of notifiable diseases—a most important matter when the difficulty of early diagnosis is taken into account. We trust that the necessity for similar action will be immediately brought to the notice of the various Public Health authorities in the vicinity of Dublin, and indeed, throughout Ireland generally. The last outbreak of small-pox in Dublin in 1894-95 did not

assume any large proportions, due doubtless to the fact that in Ireland the conscientious objector is not recognised by law and is consequently conspicuous by his absence. The recognition of the value of vaccination is one of the points on which Ireland is in advance of its sister kingdom.

Another Medical V.C.

THE King has been pleased to confer the Victoria Cross on Captain T. J. Crean, 1st Imperial Light Horse, for conspicuous gallantry in South Africa. Captain Crean, during the action with De Wet at Tygerskloof, on December 18th last, continued to attend to the wounded in the firing line, under heavy fire at only 150 yards range, after he had himself been wounded, and only desisted when he was hit a second time, and, as it was at first thought, mortally wounded. Captain Crean whose bravery has thus been suitably recognised, obtained the licences of the Irish Royal Colleges in 1896, and soon after went to the Transvaal, where he settled in practice. When the war broke out he volunteered and joined the Light Horse. In his student days he was a well-known figure in Irish athletic circles, and was especially distinguished as a football player. Happily the wound which he received at Tygerskloof was not as serious as was at first considered, and he is, we are glad to hear, now convalescent. His name is a worthy addition to the long roll of medical men who hold that most coveted of all honours—the Victoria Cross.

Tax - Produced Consumption.

IN a communication bearing on the prevalence of pulmonary tuberculosis in France, Dr. Leon Bonnet points out that while in England, the land of fog, the annual deaths from this disease number some 50,000, in France, with its, in many parts, admirable climate, and approximately the same population, the annual loss under this head is 150,000. It is only natural that he should ask himself the reason for this terrible mortality. As might be anticipated, the presumable causes are several. First there is the fact that in point of public and individual hygiene France is far behind England, the conditions of existence under which the working classes live in the great cities being often little short of disgraceful. Then there is the comparatively high cost of food: meat, butter, tea, sugar, &c., cost nearly twice the price in France of those which obtain in England, and this is largely due to the spirit of protectionism which is rampant in French political circles. It is a commonplace of knowledge that an abundant alimentation is one of the best prophylactics against tuberculous invasion and as wages generally are lower in France than in England it is obvious that the French working classes are comparatively badly off in this respect. If it were not for the thrift and culinary resources of the French housewife the conditions of existence would be even more to their disadvantage. Another cause, to which Dr. Bonnet does not allude, is the steadily

increasing consumption of alcohol which, when taken in excess, debilitates the organism and renders it an easy prey to the ubiquitous microbe. A system of taxation which strikes at the foundation of the national health stands self-condemned, and this is an instance in which the physician must needs enter upon the domain of politics.

More Influenza.

INFLUENZA is again raging throughout the United Kingdom, and may be said to be as bad as it has ever been during the past ten or twelve years, that is to say, so far as the actual numbers attacked are concerned. Happily the enemy appears to have had its claws somewhat blunted by long use, for the present form of the malady is for the most part extremely mild. For all that, it will be well for the very young and the aged and the weakly of all ages to nurse themselves carefully when attacked by this subtle and dangerous disorder. During the present outburst, which is of a wholesale nature, it will be wise to regard every serious "cold" or respiratory trouble as a probable case of influenza, and to take steps accordingly. Fortunately the remedy is in the hands of everyone who has strength of will enough to stay at home and court the grateful ministrings of rest and warmth, with a moderate gentle stimulation of the port wine negus and whisky toddy order. It is devoutly to be hoped that we are nearing the end of the prolonged and disastrous epidemic wave of influenza that for years past has periodically swept over the country.

Military Minor Surgery.

ON many occasions we have insisted on the importance to soldiers of the proper treatment of dental defects, and something has already been attempted in the direction of providing adequate dental treatment. It is obvious that a raging toothache must materially impair the efficiency of the bravest soldier, were it only by preventing his enjoying his well-earned and often scanty repose at such times as the bugle sounds truce. In reality the effects are even more serious, because bad teeth may render him unable to avail himself of the hardy fare which falls to his lot in the field. Instead of refusing men on account of dental caries, it would be more reasonable to encourage them to acquire substitutes which are not liable to the drawbacks attending the natural article. Important as are the teeth it is probable that the feet are even more essential to his combative efficiency; yet scant attention has been paid in the past to the comfort of this part of his outfit. Comfortable boots and cleanliness are the key to the prevention of the diseases to which the soldier's foot is liable. Cleanliness may be made a matter of military discipline, and approximately fitting boots are also within the reach of administrative possibility. There remain the more technical attentions which tend to avert locomotor incapacity in the domain of chiropody. An excellent little manual has just been issued by the War Office for the instruction of regimental chiropodists, and if the directions therein very clearly set forth are followed, this source of disable-

ment ought not in future to constitute a tangible source of weakness in the field.

"Coming-of-Age" of the N.S.A.

THE National Skating Association of Great Britain has been celebrating its twenty-first birthday. Skating in all its forms has been demonstrated and enjoyed at Niagara, and at the rooms of the Alpine Club a most interesting exhibition of skates and skating materials has been held. We congratulate Dr. G. H. Fowler and his colleagues on the success of the celebration, and trust that it will have brought home to the English mind the physical advantages which accrue from the pursuit of such a fascinating and health-giving sport. On medical grounds we contend that skating is one of the most desirable forms of exercise for the training of muscle and nerve, and the reinvigoration of the tissues generally. If our busy consultants and overworked practitioners would only take a mid-winter holiday and give a fortnight annually to skating at Davos, St. Moritz, Hamar, Stockholm, or elsewhere, they would run a better chance of being "healthy, wealthy, and wise."

The Indiscretions of "What's What."

IN a former number we referred to the indiscretions of the author of "What's What" in giving a list of medical men he considered deserving of his "recommendation." We are glad to see that Mr. Watson Cheyne, in a clear and courteous letter, strongly condemns Mr. Harry Quilter's foolish and unkind paragraph, showing that such is likely to cause irreparable damage to the gentleman "recommended." The author of "What's What" in reply indicates that he is unconvinced that it is wrong to inform the public on these matters, and he does not think that the family medical man is in all cases the most fitting person to advise regarding the choice of a consultant. He, however, will consider the wisdom of relinquishing his self-selected speciality of adviser of the public in the choice of medical specialists. We hope to hear no more of the indiscretions of "What's What" even should that remarkable work reach the distinction of a second edition.

The British Medical Picnic.

THE seventieth annual picnic of the British Medical Association is to take place in Cottonopolis, commencing July 29th. Mr. Walter Whitehead is President-Elect. The distinguished officers of the various sections have been chosen. It is rather striking to note to what an extent "home talent" has been pressed into the service. Sixteen sections have been brought into being. "Reforms" are to be allowed "high revels" in a section on Ethics (*sic*), of which Dr. James Brassey Brierley is one of the honorary secretaries. The Address in Medicine is to be given by a distinguished Lancastrian, Sir Thomas Barlow; and, in spite of "war's alarms," Professor Japp Sinclair is to give the Address in Obstetrics. It is long since the British Medical Association honoured Manchester with a visit, and the gathering should be "numerous and influential."

American Specialists in Ireland.

MADAME LILLIAN, the great American Herbalist and Electro-Therapeutist, her husband and daughter, whose arrest at Galway on the charge of obtaining money by false pretences we recorded in our last issue, appear to have had a lucrative "practice" in the west of Ireland. From the evidence given before the magistrate, it appears that the Lillians following their customary procedure, delivered open air lectures on medical subjects at Ennistymon, about the 15th October last, from a four-wheeled wagonette. They also distributed handbills which had reference to Madame Lillian or Emily Lillian, who was described as a "medical doctor," and better than any doctor, further, the latter were described as "poisoners." The handbills also gave forth that Madame Lillian was able to cure gout, rheumatism, and all complaints. Influenced by this, a farmer living at Ennistymon brought his wife to Madame Lillian, because, as he stated, he believed she was a doctor and qualified to cure her. Madame Lillian then told the husband that she was a doctor and could cure his wife. She asked for half-a-crown for the examination, and subsequently said that she would cure the patient for £5. This was paid, and in return the husband received four bottles, two of which were to be taken internally and two externally. Madame Lillian subsequently saw the wife twice, and then left the town. As the medicine had no effect on the patient the police were communicated with, with the result that the whole Lillian family were arrested. The male prisoner stated that he is a fully qualified medical man; we cannot, however, find his name in the *Medical Register*. The prisoners have been remanded.

Suggested Surgical Operation for Mitral Stenosis.

THERE is no more progressive art than that of modern surgery, which has gradually taken in hand every organ of the human body. Of all the fresh fields thus opened up none has more completely reversed the traditions of former times than that which deals with the cardiac region. No modern surgeon would hesitate for a moment in freely draining the pericardium for dropsical and suppurative conditions, or in exposing and suturing non-penetrating wounds of the heart itself. A far more daring procedure has been recently suggested by a physician, Sir Lauder Brunton. Struck with a disproportion between the resistance offered by extreme mitral obstruction, and the ease with which the obstructed valve could be relieved *post mortem* by a simple incision, he determined to try if a similar proceeding could not be conducted on the living mammalian heart. Unfortunately he has not found time personally to carry out experiments on the lower animals. There are many competent investigators, however, in whose hands the matter may be entrusted with entire confidence. The risk is not great in exposing the heart, and although the difficulties would clearly be great in penetrating the

wall of the heart with a fine knife, chiefly because of the cardiac and respiratory movements, the matter is, nevertheless, not hopeless. Nor is it likely there would be any serious hæmorrhage from a minute puncture of the ventricle. Sir Lauder Brunton is to be congratulated on a suggestion which, whether it prove fruitful or otherwise, is worthy of a brilliant reputation.

Accidental Poisoning of a Small-pox Patient.

AN unfortunate occurrence was reported last week at the small-pox isolation hospital at Orsett, Essex, the moral of which may be taken to heart by every local sanitary authority in the United Kingdom. The unfortunate victim was a patient to whom the nurse in attendance administered a dose of carbolic acid in mistake for his ordinary physio. From the facts of the case as reported it is safe to assume that the poisonous fluid was not in a specially constructed poison bottle, although actually in use in a hospital ward. It is to be hoped that coroners will in future lay this aspect of the question clearly and emphatically before their juries. Any hospital, whether public or private, that fails to adopt the simple precaution of keeping its poisons in poison bottles of distinctive shape should be held answerable for the consequences. Indeed, as things go, it is open to question whether the Orsett Hospital would not be liable for heavy damages if an action were brought by the relatives of the unfortunate victim of "misadventure." It seems clear enough that if the executive of a hospital fail to take a simple precaution whereby a poison bottle could not be handled unknowingly by a nurse, then such neglect is more or less culpable. A few actions at law on the part of bereaved relatives would soon bring about a change of attitude on the part of hospital authorities generally on a small but important point of administration.

An Up-to-Date Surgeon.

DR. DOYEN, of Paris, has availed himself of an almost unrivalled opportunity to court publicity by his sensational operation on the Hindoo twins, the details whereof have been obligingly placed at the disposal of the lay Press *urbi et orbi*. To enhance the interest of the occasion the details of the operation were preserved for contemporaneous posterity by the aid of the cinematograph, a device of which Dr. Doyen has shown himself *friand* on other occasions. The operation, if a bold one, presented no points of particular interest, and when last heard of one of the separated twins has since died, viz., the one on account of whose illness the operation was undertaken; the surviving twin is progressing favourably.

THE Emperor of Germany has expressed his intention of opposing the spread of so-called Christian Science and similar movements in the Fatherland. It is to be regretted that English custom does not permit the King to openly condemn the many forms of quackery and pseudo-science so rampant in this country at the present time.

Ophthalmoscopic Examination of Animals.

DR. GEORGE LINDSAY JOHNSON'S beautiful work on the Comparative Anatomy of the Mammalian Eye, chiefly based on ophthalmoscopic examination, and issued in the Philosophical Transactions of the Royal Society of London, may be commended to the study of anti-vivisectionists as evidence of the courage and enthusiasm which science demands in a whole heart pursuit for accurate knowledge. In a series of admirably executed plates, illustrations are given of the fundus oculi of monkeys, Australian fruit bat, the common seal, striped hyæna, Bactrian camel, Indian rhinoceros, Brazilian porcupine, rat-kangaroo, the Virginian opossum, and other such pets as most anti-vivisectionists would enjoy lavishing their sympathies upon through strong bars.

The Neurone Theory.

WALDEYER'S neurone theory is a widely popular one. The neurologist generally speaking, accepts it as the basis of his conception of the structure of the nervous system. Every modern text book teaches it as though it was not open to doubt; and the student swallows it as Gospel. It is therefore interesting to find that Mr. Ballance and Dr. Purves Stewart, in their admirable work on "The Healing of Nerves", recently published, throw much doubt on this concept of the nervous system as consisting of innumerable anatomically independent nervous units. They even go so far as to declare that "the neurone theory, in so far at least as it applies to the peripheral nervous system, must in our opinion, be discarded." And so the iconoclasts are not dead yet.

THE anniversary dinner of the Medical Society of London will be held at the Whitehall Rooms of the Hôtel Métropole on Saturday, March 8th.

PERSONAL.

The appointment of Colonel Franklin as Director-General of the Indian Medical Service has been approved.

MR. ALFRED WINKFIELD, F.R.C.S., Medical Officer of Health to the City of Oxford, has had conferred upon him the degree of M.A. *honoris causa* by the University.

SIR THOMAS GALLWEY has left England to take up the duties of principal medical officer in India, with the rank of Surgeon-General, for a minimum period of three years.

SURGEON-CAPT. T. J. CREAN, of the 1st Imperial Light Horse, who was severely wounded at Tygerkloof in December, 1901, is to receive the well-merited distinction of the Victoria Cross.

MR. HERBERT STANLEY FRENCH, B.A., M.B., C.Ch. Oxon., Medical Registrar at Guy's Hospital, is the recipient of the Gillson Scholarship in Pathology for 1902 of the Society of Apothecaries.

MAJOR RONALD ROSS, Walter Myers Lecturer in the Liverpool School of Tropical Medicine, is shortly leaving for Sierra Leone on a third visit, with the object of carrying on the investigations in respect of malaria.

MR. H. W. LUCY ("Toby, M.P.," of *Punch*) has inti-

mated his intention of bequeathing £1,000 to the Westminster Hospital for the endowment of a bed for members of the Press Gallery of the House of Commons.

MR. A. PEARCE GOULD, M.S., F.R.C.S., delivered the first of the Lettsomian Lecture of the Medical Society of London on Monday last on "Certain Diseases of the Blood Vessels," this first lecture being devoted to Varicose Veins.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE LATE DR. PEEL RITCHIE.

WIDESPREAD regret was felt in Edinburgh, not only in medical circles but among the community at large, at the announcement of the death of Dr. Peel Ritchie, who passed away on the 11th inst. He was the son of a well-known Edinburgh citizen, was educated and spent his whole life in his native city, with whose Poor-law administration he was for long connected, being at the time of his death a valued and useful member of the City Parish Council. His interests were exceedingly varied, and he was a careful and accurate, though not voluminous writer, on medical topics; but perhaps the work by which he will be longest remembered is his volume on "The Early Days of the Royal College of Physicians," in which the story of that college—a history involving that of medical education in Edinburgh from its earliest foundations—is told with scholarly erudition and force. His interest in his college, however, was not primarily antiquarian; for many years its treasurer, he became, in due course, its president, and then vice-president; while, after he ceased to hold office, his matured experience and sound judgment were, even to the last, as much at the service of, as they were valued by the Fellows. Dr. Ritchie was at one time on the acting staff of the Sick Children's Hospital, and subsequently occupied the less arduous post of consulting physician. He was also associated with many other medical charities, in particular with the Royal Public Dispensary, in whose affairs he always played a prominent part. For five years previous to 1892 he was a manager of the Infirmary, and on retiring from that post he became a member of the Committee of Contributors. He was elected a Fellow of the Royal Society of Edinburgh in 1883, and was a member of many medical and other societies. A man of high attainments, yet one who devoted himself to the art rather than to the science of medicine, and, amidst the calls of a busy practice, found time and energy to devote some of his talents to the service of the community, he was highly respected both by his professional brethren and his civic colleagues, and enjoyed the confidence of all who knew him. By his death Edinburgh loses a good doctor and a good citizen.

NOTIFICATION OF CONSUMPTION IN EDINBURGH.

As a result of a special meeting of the Town Council, held on February 12th, voluntary notification of consumption was adopted by twenty votes, as against ten in favour of a motion that notification be compulsory, and that a hospital containing not more than 100 beds be provided for the reception of consumptive patients. The majority of the speeches made were in favour of compulsory notification, and the Council was practically unanimous that notification in some form should be adopted. The chief arguments against compulsory notification used were that public opinion was not ripe for it, that voluntary notification would give the desired information, and that it would be an interference with the liberty of the subject. Apparently what weighed most strongly with the majority was a disinclination to commit themselves to any scheme which would involve (as compulsory notification would practically involve) providing further hospital accommodation, until such time as some of the large undertakings which the city has on hand at pre-

sent are completed. It is very questionable whether voluntary notification will be largely taken advantage of, but it is most satisfactory to learn the unanimity with which the city's rulers agreed that some form of notification would be a good thing, and doubtless we shall, before many years have passed, have phthisis scheduled along with scarlet fever and small-pox as compulsorily notifiable.

At a meeting of the medical profession in Edinburgh, convened at the request of members of the profession by the Presidents of the two Royal Colleges, held on February 15th, it was unanimously agreed that, as the present system of reporting on morbid products by the College of Physicians laboratory was entirely satisfactory, it was unnecessary and inexpedient to transfer the work to the John Usher Institute, and that the Town Council should be petitioner in that sense.

Medical News.

THE Special Session of the General Medical Council will begin on Tuesday, 25th inst., under the presidency of Sir William Turner.

Militia and Volunteer Medical Staff Corps.

In consideration of the valuable services rendered by the Militia Medical Staff Corps and Volunteer Medical Staff Corps during the war in South Africa the King has approved the following changes in the designations of the corps and in the titles of the officers:—

Former Designation.	New Designation.
Militia Medical Staff Corps	Royal Army Medical Corps (Militia).
Volunteer Medical Staff Corps	Royal Army Medical Corps (Volunteers).
Former Title.	New Title.
Hon. Commandant	} Hon. Colonel.
Hon. Surgeon-Colonel.....	
Hon. Surgeon-Lieutenant-Colonel Commandant ...	Hon. Lieut.-Colonel Commandant.
Surgeon-Lieut.-Colonel ...	Lieutenant-Colonel.
Surgeon-Major	Major.
Surgeon-Captain	Captain.
Surgeon-Lieutenant.....	Lieutenant.

Constitution of the New Army Medical Advisory Board.

THE Secretary of State for War has selected the following eminent medical men to form the new Advisory Board for the supervision of the Army Medical Services:—Chairman: Surgeon-General W. Taylor, C.B. Director-General, Army Medical Service; Vice-Chairman: Surgeon-General A. H. Keogh, C.B., Deputy D.G., A.M.S. Members: Major W. G. McPherson, R.A.M.C., expert in sanitation. Lieutenant-Colonel D. Bruce, R.A.M.C., C.M., expert in tropical diseases. Civilian members: Dr. Chas. Bent Ball (Ireland); A. D. Fripp, Esq.; Dr. Jas. Galloway; Dr. E. C. Perry; Sir F. Treves. Representative of War Office: Colonel W. A. Dunne, C.B., A.O.M.G. Representative of India Office: Surgeon-General W. Roe and the Matron-in-Chief of the Queen Alexandra's I.M. Nursing Sisters.

An Unqualified Practitioner Censured.

A MAN called Edwards, of Listria Park, was censured by the coroner's jury last week for having medically attended a woman who subsequently died without having been seen by a medical man. He described himself as "surgery assistant" to a Dr. Southcombe, and, as a matter of fact, some of the medicine supplied by him was in Dr. Southcombe's bottles. We would commend this case to the professional organisations which take cognisance of cases of this kind with a view of further inquiry.

An Unqualified Dispenser.

THE family of Dr. O'Keeffe, of St. Helens, had a disagreeable experience a few days since, when Mrs. O'Keeffe and three children became very ill after eating some "vada" cakes. It seems that Mrs. O'Keeffe, having run short of soda, took what she supposed to be soda from a drawer in the surgery. Evidently she went astray, as shown by the inconvenient, but happily not

dangerous result. We are pleased to learn that the sufferers are now little the worse for the experience.

A Dentist Killed by a Tooth.

At an inquest held by Dr. Danford Thomas at St. Pancras last week on the body of Mr. Faulkner, a dentist, it was stated that the cause of death was the irritation set up by a tooth embedded in the small intestine.

Suicide of a Medical Assistant.

MR. PATRICK WALLIS PARK, said to belong to Athlone, Ireland, acting as assistant to Dr. Roberts, of Ruabon, North Wales, committed suicide on the 11th inst., at Ruabon, by taking poison.

Some Medical Statistics.

THE recently issued census returns give 4,801 "physicians, surgeons, and general practitioners" in London, of whom 92 are females. Of these no less than 169 male and six female foreign physicians, surgeons, and general practitioners exercise their calling in London. Of these there are 10 Russians, 9 male and 1 female; 1 Russian Pole; 10 Swedes, 7 male, 3 female; 2 Norwegians; 3 Danes; 4 Dutch; 1 Belgian; 12 French; 33 Germans, including 1 woman; 3 Austrians; 8 Swiss; 3 Spaniards; 1 Portuguese; 13 Italians, 12 male, 1 female; 2 Greeks; 3 Turks; 2 Japanese; 1 Asiatic; and 63 Americans, all men. 16,107 persons living in London are returned as "sick nurses, invalid attendants," of whom 15,844 are females; 266 "midwives" and, lastly, there are 62 female dentists.

The Jenner Institute of Preventive Medicine.

WE are requested to state that no vaccine lymph is prepared at the Jenner Institute of Preventive Medicine under the direction of the governing body of the institute, but that certain laboratories in the institute are leased to the Local Government Board and that the officers of the Board are engaged there in preparing glycerinated lymph for supplying public vaccinators only. The manufacture of calf lymph for sale is also carried on at another institute, the Jenner institute for calf lymph, situated in Battersea, but that Institute is in no way connected with the Jenner Institute of Preventive Medicine.

International Congress of Gynecology and Obstetrics.

THE International Congress of Gynecology and Obstetrics will hold its fourth meeting in Rome from September 15th to 21st, 1902. The official languages of the Congress will be Italian, French, English, German, and Spanish. The following are the subjects proposed for discussion:—(1) The medical indications for the induction of labour; (2) hysterectomy in the treatment of puerperal infection; (3) genital tuberculosis; (4) the surgical treatment of cancer of the uterus. Professor Parguasi will be the general president of the Congress, while Professor Morisani will preside over the obstetric, and Professor Mangiagalli over the gynecological sections. The general secretary is Professor E. Pestalozza.

Dublin Death-rate.

THE deaths registered in the Dublin registration area for the week ending Saturday, February 8th, 1902, represent an annual mortality of 24.9 in every 1,000 of the population. Tuberculous disease caused 38 deaths, diseases of the respiratory system caused 26 deaths, diseases of the circulatory system caused 23 deaths. In 14 instances the cause of death was "uncertified," there having been no medical attendant during the last illness. Forty-six persons whose deaths were registered were infants, of whom 29 were under twelve months old. In the South Earl Street district, Peter Street district, and Grand Canal Street district the death-rate per 1,000 was 32 per cent., 31.2 per cent., and 26.9 per cent. respectively.

Pass Lists.

Royal College of Physicians of Ireland.

At a stated meeting of the President and Fellows held on February 14th, the following gentlemen were admitted as Licentiates in Medicine of the College:—T. Percy C. Kirkpatrick, M.D.; Francis C. Purser, M.D.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning corrected proofs.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

N. P. (Sunderland).—If a chemist dispenses morphine without a prescription he is under the obligation to observe certain formalities, failing which he renders himself liable to prosecution. Whether a civil action for damages would lie against a chemist who recklessly supplied the drug is a legal question which we cannot decide but there would seem to be *prima facie* grounds for a claim.

NUCLEUS.—The females in London exceed the males by no less than 252,371, the disproportion being slightly more marked than in 1891, though probably the difference is not more than would be accounted for by the absence on duty of a large number of males. You will find the other details you ask for in the Statistical Tables just issued by the Registrar-General.

INSOMNIA USEFULLY APPLIED.

A CORRESPONDENT who suffers from insomnia has availed himself of the opportunity thus afforded for serious thought to elucidate the following, which merit a place at the end of the next edition of "Young's Night Thoughts":—

A doctor's life is a merry one, for it consists of a daily round of visits. Visiting is a paying game, hence the term "to pay visits."

Parish doctors are on the parish. It is not surprising, therefore, to find that their patients get relief.

Practice makes perfect, and a perfect fool may make a practice, but it is not the general practice.

Surgeons have one great advantage over their brethren in other professions in that they can cut their best friends without causing offence, even though they cause bloodshed.

H. N. P.—The "Elixir" is an ordinary quack nostrum which has been "boomed" in accordance with time-honoured methods. We are not cognisant of its virtues, and cannot defer to your request for an analysis.

DR. J. H.—The matter is one upon which considerable divergence of opinion obtains, consequently whatever opinion is expressed is certain to run counter to the views held by a section of the public. The question at issue is, moreover, hardly amenable to argument, and must be decided by public opinion.

MEMO.—Your letter has been held over in the absence of the author of the paper, who is at present on the Continent. He shall be communicated with at the first opportunity.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, FEB. 19th.

POST-GRADUATE COLLEGE (West London Hospital, Hammer-smith Road, W.).—5 p.m. Mr. McAdam Eccles: Lantern Demonstrations on Hernia.

THURSDAY, FEB. 20th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Clinical Cases will be shown by Dr. J. Taylor, Dr. Morrison, Dr. Caley, Dr. Eddowes, and others.

FRIDAY, FEB. 21st.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos Street, W.).—Cases will be shown by Dr. C. O. Hawthorne, Mr. S. Stephenson, Mr. J. J. Clarke, Mr. E. W. Goble, Dr. L. C. Chaffey, and Dr. G. Carpenter. Papers:—Dr. C. N. Gwynne (Sheffield): Notes on a Case of Congenital Dilatation of the Sigmoid Flexure of the Colon.—Dr. J. P. Parkinson: The Local Treatment of Adenoids.

WEDNESDAY, FEB. 26th.

HUNTERIAN SOCIETY.—8.30 p.m. Mr. Reginald Harrison will deliver the Hunterian Lecture on "Some Points in Practical Surgery suggested by the Study of the Life and Work of John Hunter."

DUBLIN.

THURSDAY, FEB. 20th.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.

DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION (Trinity Hall, Trinity College).—8.30 p.m.

FRIDAY, FEB. 21st.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Pathology, College of Surgeons, 8.30 p.m.

Appointments.

AWDRY, WALTER ROBERT, M.B.Durh., M.R.C.S., Honorary Medical Officer to the Berkeley Cottage Hospital.

BATTEN, RAYNER WINTERBOTHAM, M.D.Lond., F.R.C.P., M.R.C.S., Honorary Consulting Physician to the Berkeley Cottage Hospital.
BRUNYATT, T. T., M.A., M.D.Oxon., Physician to St. Bartholomew's Hospital, Rochester.
JACOBS, J. M. O., L.D.S.Eng., Honorary Dental Surgeon to Queen Adelaide's Dispensary, Pollard Row, Bethnal Green.
MCCANN, DR. A. E., Medical Officer of Kitteraggar, Ballynagass, has been appointed Medical Officer to the Mountmellick Workhouse Infirmary.
O'BRIEN, DR. M. J., Medical Officer to the Mountmellick Dispensary District.
PADWICK, J. C., M.R.C.S., L.R.C.P., Medical Officer of Health of Bridgnorth Rural District.
PITCAIRN, G. K., M.B., M.S. Edin., Medical Officer for Littleborough.
POWELL, W. WYNDEAM, F.R.C.S., Surgeon to the Westminster General Dispensary.
SHAW, JOHN EDWARD, M.B., C.M. Edin., Honorary Physician to the Clifton (Bristol) Dispensary.
SPENCE, BASIL A., M.B., Ch.B. Edin., Dispensary Surgeon to the Bradford Royal Infirmary.
STEVENS, W. MITCHELL, M.D.Lond., L.R.C.P.Lond., M.R.C.S., Honorary Assistant Physician to the Cardiff Infirmary.
TURPIN, D. W. M., L.R.C.C.P., L.R.C.S.Irel., District Medical Officer of Shardlow Union.
VACHELL, HERBERT REDWOOD, M.D., C.M.Aberd., M.R.C.S., L.S.A., Honorary Physician to the Cardiff Infirmary.
WEARNE, WALTER, M.R.C.S., L.S.A., Medical Officer to the Helston (Cornwall) Public Dispensary.
WHEATLEY, JAMES, M.D.Lond., Medical Officer of Health to the Shropshire County Council.

Vacancies.

Borough Hospital, Bootle, Liverpool.—Senior Resident. Salary £100 per annum, with board and laundry. Applications to the Secretary.
Brentford Union.—Assistant Medical Superintendent. Salary £100 per annum, with furnished apartments in the Infirmary, rations, washing, &c. Applications to William Stephens, Clerk to the Guardians, Union Offices, Isleworth, W.
Brentford Union, Dispenser. Salary £100 per annum, with dinner and tea daily. Applications immediately to William Stephens, Clerk, Union Offices, Isleworth, W.
Carlou Union.—Qualified Nurse. Salary £25 per annum, with rations and apartments; also a Probationer as Assistant Nurse. Salary £10 per annum, with rations and accommodation. Applications to John Geo. Glover, Clerk of the Union. (See Advt.)
City of Liverpool.—Infectious Diseases Hospital, Parkhill.—Assistant Resident Medical Officer. Salary £130 per annum, with board, washing, and lodging at the Hospital. Applications to the Town Clerk, Municipal Offices, Liverpool, immediately.
County Borough of Blackburn.—Medical Officer of Health. Salary £250 per annum. Applications to Robert E. Fox, Town Clerk, Town Hall, Blackburn.
Durham County Asylum.—Junior Assistant Medical Officer. Salary £150, with board, apartments, laundry, and attendance. Applications to the Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.
Durham County Hospital.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to Wm. R. Wilson, Secretary, 684, Sadler Street Durham.
Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £30 per annum. Applications to S. J. Leonard, Clerk to the Hospital. (See Advt.)
Lancashire County Asylum, Winwick, Newton-le-Willows.—Assistant Medical Officer. Salary commence at £150 per annum, with furnished apartments, board, attendance, and washing. Applications to the Medical Superintendent immediately.
Manchester School Board.—Medical Officer. Salary £250 per annum. Applications to the Clerk of the Board, School Board Offices, Deansgate, Manchester.
Rural District of Doncaster.—Medical Officer of Health. Salary £300 per annum. Applications immediately (endorsed "Medical Officer") to F. E. Nicholson, Solicitor, Clerk to the Council, Union Offices, High Street, Doncaster.
Tottenham Urban District Council.—Medical Officer of Health. Salary £500 per annum. Applications to E. Crowne, Clerk of the Council, Coombes Croft House, 712, High Road, Tottenham.
Warneford Hospital.—House Surgeon. Salary £100 per annum, with board, washing, and apartments. Applications immediately to Richard J. Coles, Secretary.
Weston-super-Mare Hospital.—House Surgeon. Salary £100 per annum, with board and residence in the Hospital. Applications immediately to the Honorary Secretary not later than Tuesday, the 25th inst.

Births.

FISHER.—On Feb. 10th, at Sittingbourne, Kent, the wife of H. Holdrich Fisher, M.D.Lond., of a son.
YELF.—On Feb. 12th, at Bengal House, Moreton-in-Marsh, the wife of Robert E. B. Yelf, M.B. and C.M., of a daughter.

Deaths.

FORT.—On Feb. 10th, at Standerton, of enteric fever, Percy Reginald Fort, L.B.C.P.Lond., aged 28 years.
MACNAMARA.—On Feb. 11th, at 50, Viale Margherita Florence, Dr. William Macnamara, Deputy Surgeon-General in British Medical Service (retired), aged 73.

MODERN GYNÆCOLOGY.

ABSTRACT OF PRESIDENTIAL ADDRESS DELIVERED
BEFORE THE BRITISH GYNÆCOLOGICAL SOCIETY.

By J. HALLIDAY CROOM, M.D., F.R.C.P.,
F.R.C.S.Ed.,

Physician to, and Clinical Lecturer on Diseases of Women, to the
Royal Infirmary, Edinburgh.

THE lecturer after reviewing the progress of obstetrics and contrasting it as a science with gynecology, proceeded to discuss what, he said, used to be a vexed question, viz., the removal of the ovaries for inflammatory disease. That, he observed, we must now regard as having assumed a definite position, and we note with satisfaction that the indiscriminate removal of the ovaries for all sorts of inflammatory conditions has fortunately ceased, and this is only rational, for we must ever bear in our minds that in dealing with diseases of the reproductive system in women, we are dealing with organs which themselves perform a function and go through a course of changes which are unknown in any other organ in the body. Menstruation, as you know very well, is a function which has no counterpart in human economy. The relation between rest and pain is one of the best recognised axioms in surgery. To rest an organ is to relieve it. One of the greatest difficulties in dealing with diseases of the heart is that the organ is never at rest. One of the difficulties in dealing with the bladder is that it is never at rest; and so on with the stomach, and various other organs. But apart altogether from the total unrest of these organs, we have superadded in the reproductive system not only a constant cycle of changes, but also an entire renewal of the lining membrane of the uterus every month. Whether we believe in the theory of Sir John Williams that the whole of the membrane is shed off, or in Kunderab Engelmann's that the whole of the mucosa is shed off, or Moricke's theory that none is shed off at all, the fact remains that a very profound and marked change takes place in this membrane monthly. If we recollect further the changes in the Fallopian tubes, and the remarkable changes in ovulation, if we further consider that the line of demarcation between physiology and pathology is very dimly marked, if the following be accepted as a fair representation of what occurs in menstruation—namely, that the mucous membrane becomes swollen, puckered, thrown into folds and roughened; that the orifices of the uterine follicles, before hardly discernible, are easily seen with the naked eye, that the deeply injected capillaries are seen running in lozenge-shaped loops round the follicular openings, that the swelling of the mucosa affects all its elements, that there is a proliferation of the epithelial cells, on the three expanding surfaces, as well as of the lining of the follicles, that the inter-glandular connective tissue shows increase of the number and size of the corpuscles; if we further consider this hyperplasia of the uterine mucosa reaches its height when the catamenia is due, that the cavity of the uterus is now entirely filled up,

and that when the day has arrived the mucosa may be said to be in a state resembling acute catarrh, that the cellular elements near the surface become the seat of cloudy swelling, that the connective tissue corpuscles become swollen and cloudy, that the epithelium within the follicles becomes also cloudy; then with a step further fatty degeneration sets in, that the disintegrated elements give way, capillary tubes are broken open, follicular walls give way, and that uterine contraction takes place and drives the blood from the muscular wall into the mucous membrane, and so hæmorrhage sets in. This is a very gentle passage from physiology to pathology, and almost what one might call a pathological condition occurring monthly. We must consider it a monthly miniature pregnancy, for weeks a *preparation*, for days an *anticipation*, and the hæmorrhages as the tears the uterus sheds of *disappointment*. If we consider this matter there will be very little difficulty in understanding why diseases of the uterus and ovaries do not lend themselves so readily to cure. And this, it seems to me, is a matter that is so often overlooked in treating these diseases. It is, no doubt, perfectly true that in those persons who are favourably situated, and in whom the condition of inflammation superadded to the ordinary menstrual changes can be minimised by rest, mental, physical, and sexual, the cure of inflammatory conditions can be to a very great extent achieved. But there is, and always must be, a large class of the community to which these conditions of rest are inapplicable, and to whom the reproduction of the species is unnecessary, and to those cases therefore there will always be the reasonably warrantable surgical interference. In respect of the dysmenorrhœa associated with these conditions, that, likewise in those who are in circumstances to undergo it, will always be amenable to local, though not surgical, treatment, but for dysmenorrhœa and that only, removal of the ovaries for inflammatory conditions is a question of very serious and weighty consideration, and demands the most careful safeguarding.

I would like to divide the surgical, gynecological, interference, into at least three classes. The first class are those which include, to begin with, ovariectomy. An ovarian tumour, no matter what its nature or what its size, unquestionably means ill-health and almost certain death, and therefore beyond any possibility of a doubt it ought to be removed. Experience has taught us that anything like tampering or temporising with an ovarian tumour is a mistake, and after its diagnosis its removal becomes imperative. In the same class I would include all forms of pelvic suppuration; whether suppurative be in the tube or in the broad ligament, there can be no question at all that true surgery demands that the suppurating mass ought to be removed without delay, and the vaginal route has shown us that this can be done with the utmost safety and with most satisfactory results. Once more in this category I would place extra-uterine pregnancy. Gynecology has shown within very recent years no more remarkable life-saving operation than that of dealing with tubal pregnancy. The clearing up of extra-uterine pregnancy has undoubtedly been one of the most noteworthy advances in pathology, anatomy, and surgical procedure

that the last thirty years have shown. Till the clearing up of this question, hæmatoceles, so-called, were attributed to all sorts of causes, but we now know that the commonest cause of hæmatocele, whether the hæmatocele be extra-peritoneal or intra-peritoneal, is an extra-uterine pregnancy. The clearing up of the question of extra-uterine pregnancy has been nothing less than remarkable. We now can exclude an ovarian pregnancy practically, a primary abdominal pregnancy practically, and reduce such pregnancy to tubal, differentiating the three varieties, interstitial, infundibular and ampullary, and it is practically in the two latter that surgical interference has become so striking.

That many cases of extra-uterine pregnancy, whether in the form of tubal abortions or in the form of very early tubal pregnancies, are absorbed, I have no doubt: but when a tubal pregnancy has become a question of diagnosis before rupture, which can now with improved knowledge become almost an absolutely ascertained fact, its removal becomes an urgent necessity, and if it be left to go on to rupture, surgical interference, if promptly had recourse to, offers in most cases the only possibility of cure. To these I might add, of course, the operation of Cæsarian section. These sets of conditions seem to me those in which there is no option whatever of surgical interference, and which the brilliant records of the past thirty years justify us in adopting. The surgical method is the only method of effecting a reasonable cure, and therefore for the preservation of life it is necessary that the patient run the risk of the operation, or else face the alternative of death.

The most severe critic of surgical gynaecology can never for a moment deny that the latter half of the past century will ever be remarkable for these *three* great triumphs of surgical art—triumphs which have, as all true surgery should have for its aim, not only the alleviation of suffering but the distinct prolongation of healthy life. With regard to these *three* conditions, at least, there can be no manner of doubt. All the three are epoch-making events in the progress of gynaecology.

Let us look now at another class of disease in which surgery claims its triumphs as well. There is no form of tumour that is more common than the various varieties of fibroids. This is neither the time nor the place to discuss the varieties of them; but I think I may safely say that their influence upon the system is mainly either mechanical, by pressing on neighbouring organs, or by causing hæmorrhage they reduce the patient and make her liable to other intercurrent diseases. It is an interesting fact that those that are most hæmorrhagic are usually the smaller, which can be dealt with readily enough, and which have been known and recognised to gynaecological surgery since its commencement, I mean polypi, and polypoid fibroids, but the effect of pressure say, on the ureter, renders them a very serious complication indeed, not to speak of the degenerative changes which render removal imperative. In judging of them it is not only or always that hæmorrhage is the criterion, but rather their recrudescence in later life, or their rapidity of growth which must be our criterion in judging of them. In the larger tumours, especially those that press inordinately on organs, hæmorrhage is not the prominent feature. It is but seldom that a fibroid, considering their enormous frequency, is found to absolutely shorten life. It is very seldom one can point to a death directly from a fibroid. Hence, therefore, gentlemen, in dealing with fibroids we have got to keep before us distinctly that the surgical method of dealing with them is by no means an absolute necessity, or in other words, the mere fact that a woman is the subject of fibroid tumours does not imply that she is necessarily an appropriate subject for surgical operation. It is often, very often, an operation of selection, of preference; an operation done with a view to aid the patient's comfort, seldom to save her life. Now, in dealing with these benign, homogeneous tumours surgery is rapidly reaching perfection. I do not wish to detain you by going into any details of the various methods of removing fibroid tumours, or operations on them, either by hysterectomy, or myomeotomy, but the performance of a hysterectomy by Kelly or Doyen, or Segond, is no doubt one of

the most magnificent surgical sights one can see. The rapidity with which it is done, the little loss of blood, is little short of marvellous. But then we must remember that the operation is undertaken for what may be regarded, in the vast majority of cases, as a practically harmless disease. There is a principle laid down by some surgeons that everything that is unnecessary or redundant should be removed. Some have gone as far as to say that because a uterus has ceased functioning it may as well be removed. Some have gone as far as to say that if you have a redundant piece of uterus it had best be removed, because it is always a focus for morbid action. But surely this is a principle which can be carried too far, and when you consider the risks of the operation, the mental distress a woman must go through before the operation is undertaken, and the awful discomforts afterwards, not to speak of the mental effects of the removal of the entire uterus, I think these operations ought to be carried out with due regard to their absolute necessity. I have visited many clinics at home and abroad, and I am bound to say that I saw fibroids removed constantly, without any obvious reason whatever, but simply because they are fibroids. A varicocele is a morbid condition of matters, but everybody does not wish a varicocele interfered with unless it gives rise to painful symptoms. A floating kidney is no doubt a troublesome thing, but until it gives rise to troublesome symptoms one does not choose to have a lumbar incision, and the kidney sewn up. A retroverted uterus is sometimes a source of trouble, but surely one does not open the abdomen and perform ventrofixation for every retroverted uterus. And so it is with such harmless tumours as fibroids.

I have not referred specially to whether fibroids are to be dealt with by the abdominal or vaginal route. In either case the advances of surgery have been most remarkable, but perhaps the advance of vaginal hysterectomy has been as great and as marked as the advance of abdominal hysterectomy, and that brings me to the third class of cases with which I specially here wish to deal, and which are, as the years go on, increasingly urgent, that is to say, the dealing with uterine cancer. No doubt in a suitable case uterine cancer, whether of the cervix, but preferable of the fundus, can be dealt with with ease and satisfaction. The operations of Segond and Doyen have rendered this an absolutely safe procedure. The operation is performed constantly by all of us who are engaged in this department of work, and when we consider the enormous prevalence of cancer of the uterus, it is not matter for surprise that we should all be anxious to do our best for the unfortunate sufferers. After mammary cancer the uterus is by far the most frequent seat. I believe I state the case very much under the truth when I say at the present moment there are at least 8,000, probably a great many more, suffering from uterine cancer in the United Kingdom. Of all women who die of cancer one-third die of cancer of the uterus and the cervix, like other ostia such as lip and pylorus cæcum and rectum is a frequent seat of it. Alas! there can be no question that it is very considerably on the increase. According to the Registrar's returns for 1895, out of a million population 755 died of cancer. Whatever theory one holds as to the essential nature of cancer, whether the evolution theory or the parasitic theory, it matters very little, so far as we at present know, in the ultimate issue of operative interference. No wonder that we have recourse to every suggestion with a view to relieve its agonies and avert its inevitably fatal result. No wonder that the best of men are engaged every day in investigating its nature and devising remedies, local and general, medical and surgical, for its relief and cure. But what I am concerned with here is the surgical interference by means of vaginal hysterectomy. I have just said that there is no more satisfactory, no more rapid, no more uncomplicated operation when carefully performed than vaginal hysterectomy, so long as the uterus is of moderate dimensions and fairly mobile. Here we have before us an operation undertaken for an inevitably fatal disease, and such diseases as ovarian tumours, tubal pregnancies, and

pelvic suppurations sink into insignificance in face of this dire and fatal disease. An ovarian tumour may last long enough and be relieved; an extra-uterine pregnancy may sometimes come to a happy issue without an operation, and a pelvic suppuration may itself burst and get spontaneous relief, but, alas! no such hope can be held out for cancer. Therefore, we are bound to try every means in our power by surgery to eradicate this disease, and as yet there has nothing better been suggested than vaginal hysterectomy, except leaving the case alone. I have elsewhere published in detail my results in vaginal hysterectomy undertaken for cancer, cases selected on the most favourable terms, and yet I have been unable to show a prolongation of life, or indeed an easier death. Others have been more fortunate. Where the uterus is movable, where the bladder is unaffected, and where it is possible to be sure of that, where there are no infiltrated glands, if ever by any possible chance we can be sure of this, which I think is impossible, and best of all when the disease is primary and limited to the fundus, there is no question that operation is desirable; but where the disease has advanced beyond these limits it is useless, and worse than useless, to attempt any operative interference whatever; and, under such circumstances, in my humble opinion the patient is best to be left alone, and die in euthanasia through opium.

The prognosis in surgical interference in cancer is a purely anatomical one.

1. In an organ such as the bladder, which is essential to the economy, only palliation, and that to a limited degree, is possible.

2. I take it that it is a well-recognised axiom in surgery, that in dealing with cancer the chain of glands nearest the affected parts must be cleared away. Where the lymphatics and glands, say in a case of mammary cancer, can be completely cleared out, for no operation on the mamma can be considered complete without this, or say even in cancer of the lip, the old V-shaped incision is not enough, the sub-maxillary glands must be removed as well; in these cases prognosis for operation is excellent. But in the mamma only forty per cent. even then offer so-called permanent cure in the breast, though recurrence may be common after three years somewhere else. For it must ever be kept in view that infiltrated glands do not require to be seen or felt. They may show no naked suspicious appearances whatever, and microscopic examination has often shown them to be the seat of infiltration.

This is the initial difficulty in dealing with the uterus. To this all operators are now turning their attention, for even in early cases the glands are often affected. The two desiderata in dealing with a cancerous uterus is first and mainly, early recognition, and the possibility of dealing thoroughly and efficiently with the glands and lymphatics. As yet no very satisfactory method of accomplishing this has been devised either by the abdominal or vaginal route. It is most remarkable, speaking entirely from experience as gynecologist to a large hospital, how very few cases present themselves in such a condition as to render even the remotest hope of a successful removal. Personally the great majority of cases in which I have thought it worth while to perform the operation have been in private practice. The uterus and annexa, unlike the bladder, not being essential to the life of the patient, ought to be successfully dealt with in malignant disease, were it not for the question of the glands and lymphatics.

Hitherto hysterectomy for cancer has not been by any means a brilliant success, so far as the ultimate issue of the case is concerned, for the reasons I have just mentioned, viz., early recognition, removal of lymphatics and glands. This is certain that, while some are relieved, and some may enjoy a considerable period of immunity, it is never possible to promise a cure in any individual case.

I am well aware that this period has been traversed, but I will only say this, that I can point to cases now that have been diagnosed microscopically as uterine cancer and been left alone, who have lived beyond the usual term of cancerous patients, three four years, one five years, and who have performed their duties more

or less satisfactorily during that time, and died comparatively easy deaths; whereas I can point to others on whom operative interference was had recourse to, who have died shortly, say within a year, afterwards, from peritoneal cancer. Nothing can exceed the beautiful technique of Kelly, Segond, and Doyen, but even Segond, who was among the originators of vaginal hysterectomy, has arrived at a very much similar opinion. In suitable cases we must go on operating until we succeed, but in those cases which are advanced, and in which statistics have shown us that operations do not prolong life or lessen suffering, surgical interference should be absolutely withheld. What the future holds in store for us with regard to the treatment of cancer none of us can say, but so far as our knowledge at present goes, surgical interference, except in the earliest and most favourable cases, is unavailing. It is needless for us to compare mammary cancer with uterine. The two conditions have nothing in common. Mammary cancer can be, and usually is, recognised early, and the statistics give the most satisfactory results; but uterine cancer is unfortunately very different; pains, and hæmorrhages, and discharges go on for long before the patient seeks advice, and the most of them therefore when they come under the charge of the gynecologist are too far advanced to offer the chance to which I have just alluded.

For the present the surgical treatment of uterine cancer, unless under the most exceptional circumstances to which I have referred, is, to say the least of it, unsatisfactory, and perhaps, great though the advances and achievements of surgery have been, it is possible, nay more, likely, that the great advance will not be surgical but medical, and this hitherto unconquered foe will fall vanquished by the discovery and destruction of the bacillus. Until that time arrives vaginal hysterectomy must be persevered with in some of its many modifications.

In the adoption of our various methods of work, though some in our department be somewhat conservative and others inclined to press rapidly on and risk much, yet the end we all aim at is one, and as the end is one so plainly it is our duty and our privilege to take the best wherever we find it and to hand down the torch to our successors. "Quasi cursores vitæ lampada tradunt," and notwithstanding failures and disappointments, which must be the lot of us all, yet our watchword ought to be—

Yet do thy work, it shall succeed
In thine or in another day;
And if denied the victor's meed
Thou shalt not lack the toiler's pay.

Faith shares the future's promise; Love's
Self-offering is a triumph won;
And each good thought or action moves
The dark world nearer to the sun.

NOTES ON A CASE OF INDUCTION OF LABOUR FOLLOWED BY ENUCLEATION OF FIBROID TUMOUR FROM CERVIX. (a)

By FRED. WM. KIDD, M.D.,

Professor of Midwifery, Royal College of Surgeons, Ireland, late
Master, Coombe Hospital.

THE case which I am about to place before you presents such points of interest to the obstetrician that I have thought it worthy of bringing it before the members of this Section of the Academy. As well as the general interest in the subject it has certain peculiarities which I have not met with in any of my previous experience. I have added to my notes extracts from authorities on the subject which I hope may be of interest to some of our members.

(a) Abstract of Paper read before the Section of Obstetrics, Royal Academy of Medicine in Ireland, February 7th, 1902.

Mrs. K., *æt.* 34, mother of one child who had died, was brought to me on March 18th, 1901. She was then pregnant four and a-half months. She was complaining of sacral pains and constipation. I examined her in my study and found that she had a fibroma springing from the posterior wall of the cervix extending towards the hollow of the sacrum. It seemed to me to be about the size of a hen's egg, and to encroach very little on the cervical canal. I thought that it would be possible to deliver her with forceps without having to operate on the tumour, provided that she returned to town within three months from that date, that the tumour had not appreciably increased in the meantime (it being well known that these tumours sometimes increase enormously under the stimulus of pregnancy), and that I was successful in inducing premature labour. I wrote to her medical adviser and asked him if he would watch the patient, and by examination from time to time assure himself that the growth was not getting much larger. In case he thought it increasing at all she should be sent up to town at once. I heard nothing more about this patient until she came to town, except that she was going on well and that the growth was not appreciably enlarged, her backache and constipation had been much better and her general health had improved. On June 17th she again came to town and went into lodgings. On the succeeding day (Tuesday, the 18th), the bowels having been well cleared out, Dr. Fleming saw her with me; we both examined her very carefully and agreed that the condition afforded a good chance of being able to deliver her, and that labour should be induced. The patient having been properly prepared, a No. 9 bougie was introduced through the cervix, and then between the membranes and uterine wall until its whole length, except the head of the instrument, was within the uterus; the vagina was packed with iodoform gauze. Next morning (Wednesday, the 19th) she was found to be in labour, the gauze and bougie were removed and patient thoroughly douched. These pains were regular and dilated the os, although they were not very strong. By the evening the os was the size of a crown piece; these pains continued all Wednesday night, so that the patient could not sleep. On Thursday morning the 20th, little or no advance had been made, the os was a little bigger than the preceding night, about $1\frac{1}{2}$ ins. in diameter, admitting two fingers easily; membranes were ruptured, head presented but did not engage, owing undoubtedly, to the tumour. The patient was more or less fretful, owing to the want of sleep principally. As this condition was unsatisfactory, we now determined to put the patient under chloroform and make a thorough examination; this having been done, we found that the tumour was larger than we had at first supposed, and that it invaded more of the lower zone of the uterus than we anticipated, thus not only preventing the head from engaging in the pelvis, but preventing the cervix from dilating. Owing to the previous injury to the perineum it was found possible to introduce the whole hand into the vagina without much difficulty, and when this was done with two fingers in the os and the thumb outside, one could get the fingers above the upper border of the tumour. Having discussed the case, and the foetal heart being heard distinct and strong, it seemed that the alternative open to us was either to try enucleation of the tumour through the vagina or to proceed to coeliotomy and Caesarian section or Porro's operation. The patient refusing to go to hospital, we had to face the increased risks of septic infection where she was. So taking into account that there might be less risk if we did not open into the peritoneal cavity, also the fact that as far as we could find there was only the one tumour, we decided to try enucleation by the vagina. If we succeeded in removing the tumour, and that the premature child did not survive, yet the mother, supposing she recovered, would have a chance of having a living child should she again become pregnant. Having made our preparations, and assisted by Dr. Neill, who administered the anæsthetic, we proceeded to enucleate the tumour. The vagina having been thoroughly douched and cleansed, Dr. Fleming was able to draw down the tumour between two fingers so that I could see the

tumour at the vulva (patient was in the cross-bed and lithotomy position). The capsule of the tumour was rapidly incised, and the tumour was then enucleated by the fingers, first being caught by a vulsellum forceps. This was followed by rather profuse hæmorrhage, part of the capsule of the tumour had been torn during enucleation, as preliminary incision had not been quite long enough. This injured portion and some of the redundant tissue surrounding the tumour were cut away with scissors. Then portion of the flaps was stitched with chromicised gut, leaving sufficient aperture to introduce a packing of iodoform gauze. This was introduced after the cavity had been well cleared of any clots and thoroughly washed out with hot creolin solution, the catheter was then passed and a quarter of a grain of morphia administered in the form of a suppository. The operation of enucleation was performed about 5 or 6 o'clock in the afternoon. Pains, or in other words, uterine contractions, continued until about 1 a.m., when they ceased, and after which the patient passed a quiet night. On the following day (Friday) the iodoform gauze packing was removed and the cavity syringed with hot creolin solution. The hæmorrhage had been controlled by the packing, but recurred to a slight extent when the latter was removed. After the syringing it was again packed. No uterine pains or sensible contractions occurred at all on Friday, and the patient again passed a quiet night. There was no longer any necessity to pass the catheter, and the bowels acted after a dose of liquorice powder.

On Saturday the gauze was removed and the cavity washed out with creolin solution by means of a large Bozeman catheter. As no fresh bleeding took place at the time, the packing was not reintroduced, with the idea that the cavity would shrink up better without it. Some gauze was put loosely in upper part of vagina. On Sunday the pulse was rather quick—112, temperature 101° . Patient complained of headache. The cervix, which had been closing since Friday, would not now admit the tip of the finger. No discharge came from vagina, which was simply douched with creolin solution. Ten grs. of phenacetin had the effect of relieving the headache for the time, and the skin reacted well. Sunday night, however, the patient was very restless, and on Monday morning the temperature was again up to nearly 102° , pulse 120. Complained much of headache. There was a brownish discharge from vagina, not very profuse, but somewhat fetid. This called for an immediate exploration of the condition of the cavity. Where tumour had been the opening was found with some difficulty—it was then discovered that some further hæmorrhage must have taken place into this sac which had clotted, and the brownish discharge came from this source. The clots were turned out with the finger as well as possible, and the cavity again well washed out with creolin solution, then packed again with the iodoform gauze. This brings us to Monday; each day after this for three or four days the same treatment was adopted with the cavity, which daily contracted rapidly; the temperature, which for a couple of days remained between 101° and 102° , came down to 99° by the succeeding Saturday. The pulse remained fast at first, but came down to about 84; she complained a good deal of headache and night sweating; her strength was kept up by strong beef tea, chicken jelly, eggs, custards, egg flip, and white wine whey. She was rather a difficult patient to manage; although there was no incontinence of urine, or involuntary passage of fæces, on more than one occasion the bed was wet under her with urine, and on one occasion certainly there was some evidence of fæces also. This happened on the Saturday night following the operation, and possibly may have accounted for the condition of the patient on Sunday and Monday. The nurse in charge of the patient had been called away suddenly to see some other patient, and had left my patient in the hands of her daughter, who was only a probationer at a nursing institution, and had only then completed some weeks of training. Needless to say sepsis under those conditions was impossible; the nurse was reprimanded for leaving her patient and I must say expressed great contrition and nursed her remarkably well afterwards, but

the harm had probably been done then. On the following Sunday morning labour pains again came on, and the child was born so rapidly that I was not there until after its birth. The child, a female, was born alive. There was no trouble with the placenta and no post-partum hæmorrhage. A douche of creolin solution was given before the binder was applied. All that day she seemed very well until about 8.30 in the evening I was summoned to find she had had a severe rigor and the temperature had gone up to 106.4°, pulse 144. The uterus was well contracted. However, to be on the safe side I gave her an intra-uterine douche of creolin solution. She then got 15 grs. of phenacetin and $\frac{1}{2}$ oz. of whiskey every two hours. She complained of no pain or tenderness over the abdomen, and did not look badly. The facies was good. The temperature was taken by myself twice in the vagina so as to prevent any possibility of a mistake. Next morning her temperature was down just below 104°, pulse 120, and her headache had reappeared. Uterus well contracted, lochia good colour and good quantity. The Bozeman could only be introduced into the cavity where cyst had been. It was thoroughly syringed. Following day temperature fell to 101°, and there was some secretion in breasts. Uterus hard, involuting well; lochia still healthy; vagina still well douches. Stimulant was still administered, but in diminishing quantities. The child, which had been fed up to this on white wine whey, was now put to the breast, the breast milk being supplemented for some days by white wine whey; it ultimately was able to do with the breast milk alone, on which it thrived well. The patient's condition rapidly improved, and she was able to return to the country within four weeks of the birth of her child. For the first week she got fairly large doses of quinine—12 to 16 grs. daily for three or four days, after which the dose was gradually diminished. I heard from this patient at Christmas, and both she and her child were in perfect health. Before she went away it was very difficult indeed to see any trace of what had been done in removing the tumour. Some slight puckering and that was all.

The life-history of these uterine tumours is one of exceeding great interest to the obstetrician and operating gynecologist. As regards their etiology nothing very definite has been agreed upon, the most generally accepted theory being that of "irritation" as a provoking cause, whether that irritation arises from endometritis, metritis, gestation and parturition with septic absorption, or by the presence of some micro-organisms in the uterine walls, as has been suggested by Byford. Winckel thinks they spring from uterine interparietal blood vessels; Klebs, from the connective tissue of blood vessels; Kleinwächter (according to Martin) ascribes their parentage to a round-celled formation found along the capillaries, while W. Anderson says they are "localised or diffuse hypertrophies or developments of embryonic (mesoblastic) uterine parenchymatous tissue." A. Aubean refers them all to a syphilitic origin, but this theory cannot stand with our everyday clinical experience. Ricker, in "Virchow's Archiv," 1895, speaking of the origin of fibroids in the uterus, "thinks there is strong reason to believe myoma has usually an embryonic origin. In some cases distinct epithelial relics are found in myoma which seem to represent the remains of the primitive epithelium of Müller's duct. Relics of the Wolffian duct are decided to be found in the uterine wall. He is as certain as Coblenz as to the persistence of that duct and its relation to new growth. Abnormal ingrowths of muscle cells around the duct are represented in Ricker's drawings. Hence it is probable that every myoma originally arises from some abnormal growth of muscle around the Wolffian duct in the uterine wall or around epithelial debris from the Müllerian duct, relics which may even be distinct diverticula not entirely effaced after fusion of that duct with its fellow to form the uterus." As regards the time at which they may appear, there does not seem to be any trustworthy history of myoma in the uterus before the age of twenty. Several have been observed between twenty and twenty-five. The maximum frequency is between thirty-five and forty-five. J. Bland Sutton states that "all uterine

myomata arise during the menstrual period of life." That such growths are far more frequent than is generally supposed is proved by observations in the dissecting room. Klob, according to W. Anderson, maintains that 40 per cent. of women dying after fiftieth year have uterine fibroids. Bayle states that 20 per cent. of women over thirty-five show fibromata. Winckel, in 575 autopsies, found only 12 per cent., but age is not stated. Of 135 women under thirty-five years of age only 5 per cent. had fibroids. We see from these statistics that although authorities differ yet the rate per cent. is very high. Pozzi states that these tumours are much more frequent in black women than in white, while as exciting cause Fehling "attributes great importance to incomplete involution after labour and abortion where a sufficient period of rest is not enjoyed." Ninety per cent. of these tumours develop in the body of the uterus, 10 per cent. or less in the cervix. As to their site with regard to the cavity of the uterus F. H. Martin says 10 per cent. are submucous, 15 per cent. intramural, 20 per cent. subperitoneal, and 55 per cent. interstitial (diffuse). These tumours in their life history undergo many changes; they sometimes tend to become pedunculated, whether on the serous or mucous surface of the uterus, they may undergo necrosis, or calcification, or involution and absorption, they may become cystic or sarcomatous. Absorption or involution of these tumours often occurs when they have been associated with pregnancy, or after the menopause, when usually a general atrophy of all the genital organs takes place. The very effect of lactation on these tumours has led to experiments in that direction. Howitz Copenhagen discusses the effect of lactation in involuting the uterus after pregnancy and its power in causing diminution and absorption of myomata. He narrates the history of two patients who were under treatment for intramural tumours—both became pregnant and went to full term. One suckled her child, and in four months tumour had decreased; the other had not sufficient milk, could not nurse, and tumour was unaltered. Based upon this he experimented on seven cases who were not pregnant; he tried artificial suckling or aspiration of the nipple. In four cases secretion of milk was induced, in two cases they refused to respond to the treatment, and one was not long enough under treatment to be sure of any result. In three the tumour decidedly decreased in size, in three the measurements remained the same, in only one was hæmorrhage decreased. Aspiration lasted from "five to ten minutes morning and evening," but his intention was to try it oftener so as to imitate as nearly as possible the process of natural lactation. A greater percentage of these tumours in pregnancy is prevented by the fact that the growth predisposes to sterility by usually producing an endometritis. Lefour noted thirty-nine cases of abortion in 309 cases, and Naus recorded forty-seven abortions in 241 cases (Dorland). The number of these tumours in the uterus and their situation are of great importance to the obstetrician. Where there are many tumours the condition of pregnancy is not likely to co-exist, but if it does the risks of interference with labour or of removal of tumour is increased *pari passu* with their number. A fibroid tumour of very considerable size may grow near the fundus and give rise to very little trouble, some authorities say no trouble; for my part, however, I question this, as such tumours may interfere with the position of the child in the uterus, must interfere more or less with the regular contractions and retractions of the uterine muscular tissue, and therefore predispose to prolonged labour, and for the same reason may cause increased risk of post-partum hæmorrhage, of irregular contractions causing retention of the placenta, and later may interfere with the normal progress of involution. A tumour low down and situated on the anterior wall of the cervix is not so dangerous as one on the posterior wall, as vigorous contractions of the uterus may result in carrying it upwards out of the pelvis; whereas the sacro-vertebral angle being about 3 ins. or more higher than the upper border of symphysis pubis, if the tumour spring from the posterior wall it becomes impacted in

the hollow of the sacrum by the promontory, and obstructed labour is the result. In such a labour—should it be prolonged—the injury to the tissues owing to pressure may be such that sloughing may result. With regard to the treatments that are open to choose from, we have inducing abortion, myomectomy, enucleation (if in cervical wall), and Porro-Cæsarian. (Dorland says the mortality of those going to term is high—mothers 53 per cent., children 66 per cent.).

Kelly says questions to decide with regard to treatment are (1) whether pregnancy can occur in a given case; (2) when pregnancy exists, whether the life of the mother is in danger or not; (3) whether a living child can be carried and born at term. Kelly's own statistics prepared by Dr. J. H. Durkee 236 married women with myomatous uteri had 542 pregnancies, 402 children born at term, 140 miscarriages, average number of pregnancies for each woman was 2.03. He lays down the following axioms of treatment regarding surgical interference with the uterus before the last months of pregnancy, that is to say, before the viability of the child:—

(a) Remember two lives are involved, if possible save both, rejecting all radical measures unless symptoms be urgent. Mere prophylaxis, that is operating when there is no urgent symptom on account of dangers which may arise, has no field here.

(b) Small and medium-sized fundal fibroids do not demand operation.

(c) Intra-ligamentary and subperitoneal cervical fibroids do not demand operation, unless of such a size and so located as to encroach on pelvic room or the superior strait in such a way as to prevent labour. Pedunculated fibromata which can be pushed up into the abdomen do not justify interference during pregnancy.

(d) Interstitial tumours should not be touched if the operation can possibly be avoided for they require so much handling and suturing of the uterus that abortion almost always follows.

(e) Operations may be demanded, on account of severe pain caused by fibroid tumour.

(f) Operation may also be called for owing to rapid growth of tumour during pregnancy.

(g) Pedunculated fibroid tumours (polyps) hanging out of cervix into vagina may be removed.

(h) When the patient has gone almost to term if the fibroid masses are so large as to necessitate a subsequent hysterectomy in case they are left, then it is better to deliver the child by a Cæsarian section and to remove the uterus at the same time.

The greatest risk of error in these cases is in removing a uterus with fibroids where the tumours might at a later date be removed without the sacrifice of the uterus. A sessile tumour so placed in the pelvis as to obstruct labour may be removed without much risk of causing abortion. Kelly performed the operation three times for sessile tumour before the sixth month without interrupting pregnancy. G. Aimé and R. Frommel have extirpated intra-ligamentary myomata successfully without interrupting pregnancy. Kircheimer estimates the mortality of 18.87 in myomectomy for pedunculated fibroids and 26 per cent. in supravaginal amputation of the pregnant uterus, while premature interruption of pregnancy is as high as 40 per cent. Many others have been recorded in American literature.

In reviewing the various statistics there is of necessity considerable difference between the results of different operators and different observers, but one point is certain, and that is, that the conservative operations where both mother and child can be preserved are being accompanied by progressively improving statistics, and this result is largely due to the improvements in the technique of abdominal surgery, and a rigid adherence to the principles of asepsis. I fear I have trespassed much upon the patience of the members of this Section, and I must apologise if my communication has reached a much greater length than I originally intended.

THE PREVENTION AND TREATMENT OF DEFORMITIES RESULTING FROM FRACTURES. (a)

By J. JACKSON CLARKE, M.B.Lond., F.R.C.S.,
Senior Assistant Surgeon at the North-West London Hospital;
Assistant Surgeon at the City of London Orthopaedic Hospital.

THE treatment of fractures and deformities arising from fractures has of late years been conceived in a more liberal and scientific spirit than heretofore. This has resulted from three chief causes: (1) The freedom and enterprise conferred on surgery by antiseptic methods; (2) the proved value of early muscular movements and massage as initiated by Lucas-Championnière; and (3) the increased diagnostic powers that the surgeon possesses in the application of the Röntgen-ray process in the investigation of fractures.

That surgeons generally are alive to the modern enlargement of the subject of the treatment of recent fractures and their remoter results is amply evidenced by recent literature. (b)

The plan of cutting down and fixing fragments has been recommended for nearly all fractures. I think we shall all agree that this is going too far, but I would suggest that in all compound fractures, and in all simple fractures where some complication, such as a wounded artery or nerve, renders an incision necessary, the repair will be aided by our wiring or otherwise fixing the fragments together. Other indications for the open operation in cases of simple fracture will be mentioned below.

As an illustration of the benefit of this mode of treatment in a very bad subject—a broken-down man with severe chronic bronchitis—I may adduce the following case:—

Case of Compound Comminuted Fracture of R. Tibia and Fibula with Simple Fracture of L. Tibia and Fibula.

On November 17th, A. B., æt. 70, was admitted into the N.W.L. Hospital with history of having been run over by a tramcar.

On admission patient was suffering from a fair amount of shock, so he was put into a warm bed and hot drinks given to him.

On examination there was found to be a compound comminuted fracture of rt. tibia and fibula just below junction of middle third with lower third. There was a good deal of comminution of tibia, several pieces of bone being loose. There was a simple fracture of l. tibia and fibula. He was suffering from chronic bronchitis, there being a good deal of cough with much expectoration.

About one hour after admission patient was taken into the theatre, chloroform was given, and the seat of the compound fracture was thoroughly cleansed. The upper part of tibia had protruded, and a good deal of dirty, greasy material had been carried in. The detached pieces of bone were removed, and the ends squared and cleaned. The ends of fibula were drilled and wired, and a counter-opening was made on other side for efficient drainage, and drainage tube was inserted and wound dressed with iodoform, and put on a back splint with two side splints.

Took chloroform very well; breathing improving. Simple fracture was set on back splint with two side splints.

November 18th.—Slept well last night; no pain; pulse good; does not take food well.

19th.—Right leg dressed and drainage tube removed; leg looking very clean.

21st.—Both legs dressed; patient quite comfortable; bronchitis troublesome; taking food better.

24th.—Quite comfortable.

30th.—Cough is much better and patient sleeps well; wound is healing rapidly and there is no pain.

(a) Introduction to a discussion at the Meeting of the British Orthopaedic Society, February 15th, 1902.

(b) See, for instance, a series of papers in the *Practitioner*, Aug. and Sept., 1901.

December 4th.—Patient feels quite comfortable.

7th.—Left leg was put into a Croft's splint; other leg healing very well; patient quite comfortable.

20th.—External wound has nearly granulated to surface; wound on inside of right leg has healed.

24th.—Right leg was put up in Croft's and is being massaged and rubbed every second day; skin has not quite healed over; patient can raise his leg quite comfortably.

January 6th.—Now gets out of bed on to a chair; he has very little cough now; he is not able to put any weight on to his legs.

21st.—Dismissed to-day, leg being quite healed; has been getting up every day, but afraid to put much weight on to his legs; can use crutches a little; both legs have healed in very good position.

A few weeks later the patient returned to show himself. He was then walking well without any support.

The inclusion of the prevention of deformity in cases of fracture really brings within the scope of the discussion the primary treatment. But for the present purpose some scheme of classification of the disabilities and deformities that are liable to occur after fracture is what is primarily called for to enable us to discuss this many-sided subject, and I would suggest the following as the chief factors that singly or combined form the pathological substratum in different cases:—

1. *Psychical Impressions*.—This heading may be illustrated by the experience common to most of us that a slight cut on a finger is sufficient to make us keep the damaged member tucked away in the shelter of the other digits not only till the cut is soundly healed but for a period beyond this, and only by repeated application of an intelligent will is the member brought back to its duties. In the same way many fracture-patients remain disabled simply from the persistence of the mental impression of an injury long after it is soundly repaired. These imaginary weaknesses are often intensified by the patient having in his possession a radiogram which may show sharp angular shadows at the seat of fracture, but not the callus which ensheathes them. I need not give examples of this kind of disability, but it has to be borne in mind when we are estimating the amount of real disability in any given case.

2. *Fibrous Adhesions*.—The results of organisation of blood-clot among muscles or within a joint in the neighbourhood of a fracture are familiar to every surgeon. They constitute the primary indication for early massage and early passive movements. Sir William Bennett (a) in this country has insisted on the value of these measures in the prevention of fibrous adhesions. Massage may be impossible owing to a blistered condition of the skin over the seat of fracture, but passive and aided active movements of the joints on either side of a simple fracture are nearly always practicable. Massage helps also by the relief of pain and spasm. In my experience bivalve splints of plastic material so applied as to allow of one aspect of the limb being stroked and rubbed whilst the other side is supported by the splint are of great service in enabling massage to be applied. I most frequently use household flannel and plaster of Paris (Croft's method) for this purpose.

3. *Muscular contractures* due to the prolonged maintenance of incorrect postures in a limb fixed up in splints are also familiar causes of lameness and deformity after fractures. For their prevention careful attention to posture, e.g., rectangular flexion of the ankle, and to manipulations and massage are called for; the cure is also often effected by massage, and use of the limb after recovery, but sometimes tendon-lengthening or tenotomy may be required. In this connection I may mention that in such con-

ditions our orthopaedic instruments with joints "stopped" on the side towards which the contraction has taken effect and free in the opposite direction are often of signal service.

4. *Angular Deformity from Faulty Union*.—Nowadays there is less excuse than formerly there was for such ill-results; for a radiograph taken with the limb fixed up in wooden or plaster splints will enable the surgeon, in spite of much swelling, to see whether he has succeeded in bringing the fractured surfaces into apposition. If this cannot be effected otherwise, there need be no hesitation in cutting down on the bone and, after removing clot, &c., wiring or otherwise fixing the fragments. In such operations many different devices have been employed, and it will be of service if surgeons will state their experience: Screws, metal pins, metal plates have all been used. My own experience is limited to stout silver wire, annealed by being passed through the flame and allowed to cool slowly. For remedying angular deformity osteoclasis, subcutaneous or open osteotomy may be called for. In such conditions my experience of osteoclasis is limited to cases in which manual force is sufficient to break down the callus. Subcutaneous osteotomy is followed by singularly little discomfort. Free exposure of the seat of fracture is needed when important arteries or nerves are involved.

5. *Shortening from Overlapping of Fragments*.—Illustrative cases of any success in treatment of this class of case will be of exceptional interest. Forcible extension under anaesthesia after osteotomy, followed by fixation of fragments by wiring or otherwise, is the course that in modern conditions appears to me to suggest itself. In order to aid extension myotomies, fasciotomies, and tenotomies may be necessary.

6. *Failure of Repair: Pseudarthrosis*.—But little that is new has of late come into practice in this class of cases; the important thing is to find out the cause of the failure of union. The influence of ischaemia will be referred to lower down.

7. *Exuberant Callus* may call for removal. An instance of this kind is seen in cases of fracture of either of, or both, the bones of the forearm. It is especially likely to occur in fracture of the radius above the attachment of the pronator radii teres. When a radiogram shows that this result is likely to occur it is, in my opinion, advisable to cut down and secure the bones in their proper position by wiring. If the condition is met with the bridge of callus should be fully exposed and completely removed; for this purpose I would suggest that a Gigli's wire saw would be the best instrument to use.

Fractures in the neighbourhood of joints, separation of epiphyses, and fractures into joints all call for special consideration and experience of particular cases are always of value.

8. *Separated Epiphyses*.—In young children with separated epiphyses we are not always able to rely on the Röntgen rays for help, no image of the cartilaginous epiphyses being given in the radiogram. This fact serves to remind us that this new means of diagnosis does not relieve us in any case of fracture from making a scrupulous examination of the limb. In most cases a radiogram is unnecessary; in all cases the other observations are necessary to check what, after all, is not a true photograph, but a shadow-effect that may be very misleading. Separation of the upper epiphysis of the humerus is not infrequently mistaken for dislocation; in such cases when swelling may cause difficulty in diagnosis the X-rays may be of service.

It is generally recognised that it is better, if possible, to avoid wiring in cases of separated epiphyses owing to the foreign body being liable to interfere with the growth of the bone, and in very young

(a) "The Use of Massage and Early Movements in Recent Fractures and other Injuries."

children the softness of the bone renders it difficult to put much strain on a ligature.

9. *Fractures in the Neighbourhood of Joints.*—The points raised in such cases are similar to those in which epiphyses are involved, but since they occur in older subjects the bones are firmer and there is no danger of disturbing the after-growth of the bone, so there need be no hesitation in wiring or otherwise fixing fragments when this is called for.

Fractures in the neighbourhood of joints may be complicated by dislocation, and in such cases if ordinary means fail there need be no hesitation in opening the joint to reduce the dislocation, and at the same time the fragments may be wired together as has been advocated by McBurney in cases of fracture of the upper end of the humerus complicated by dislocation of the upper fragment.

10. *Fractures involving Joints.*—Two common fractures come into this category—fracture of the patella and of the acromion. In these two fractures the facility of wiring or otherwise fixing the fragments and at the same time of removing the clot in the joint by sterile salt solution suggests the question whether open operation should not be the rule here. Before deciding on this so simple course it is, in my experience, desirable to study the condition of the patient with particular care. When the fractures arise, as is the rule, from muscular strain of ordinary degree (i.e., without the patient being loaded by carrying a weight on the shoulders) there is, I think, often some rarefaction of bone underlying the accident. Such rarefaction is commonest in patients who are inclined to gout, and these are the very individuals who do not bear urgency operations very well. In two cases that I investigated many years ago death occurred in the one during, in the other shortly after, an operation for wiring the patella. Both were men of about thirty. In the one who died under chloroform the heart was in an advanced state of true fatty degeneration. The second patient had been put to bed after operation, and recovered from the anæsthetic, when he suddenly sat bolt upright and fell back dead. I found recent emboli filling the coronary arteries. Both these men were drinkers. As instances that have come under my notice of deformities following fractures involving joints I may mention three:—

(a) Fracture into the shoulder-joint with separation of the greater tuberosity. An elderly woman met with the accident some six months previously, and had had swelling of the arm from pressure of the head of the bone on the axillary veins, and pain from pressure on the nerves of the brachial plexus. On cutting down and examining the part I had to remove the head of the bone, but the swelling of the arm persisted. In these cases it would be better in the first instance to cut down, open the joint, and wire the fragments together.

(b) A woman whose elbow was stiff, and who had lost the power of pronation and supination after a fall on the elbow some six months previously. Radiographs showed that the head of the radius was broken off in two fragments. I opened the joint from behind by chiselling through the base of the olecranon. This revealed one-third of the head of the radius fixed by adhesions between the broken surface of the neck of the radius and the humerus. I removed the fragments, wired the olecranon, and closed the skin incision. The patient has now good movement in every direction at the elbow-joint.

(c) A girl, æt. 9, brought to me with the elbow fixed in the extended position five months after an injury. A radiogram showed separation of the outer condyle, with dislocation of the ulna backwards. Under anæsthesia, I was able to improve the relative position of the fragments, and to fix the elbow at a right

angle. The child has now useful pronation and supination, but has to wear an instrument to prevent the return of a rigid extension of the arm. When her growth is completed, i.e., when she is about sixteen years old, the desirability of excision may be discussed. Recent fractures into the elbow-joint are best dealt with by the open method, wiring or excision being done according to circumstances. Bony ankylosis is most likely to occur where supuration has taken place in cases of compound fracture involving the joint.

11. *Ischæmic Contracture.*—This troublesome deformity may exist alone, or may complicate other deformities after fracture. It is commonest after fractures of the humerus. When it forms the only element in the deformity we have a valuable means of alleviating the resulting disability in tendon-elongation practised on all the flexor tendons above the wrist. This delicate and prolonged operation should, in my opinion, never be done unless some useful voluntary power remains, and until all that can be gained by massage, &c., has been tried. If an attempt is made to remedy the deformity by removing parts of the radius and ulna, an ununited fracture is the result.

HÆMORRHAGES FROM THE EAR IN HÆMOPHILIA.

By DR. TOMKA SAMU,

Physician to the St. Janos' Hospital, Budapest.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS
AND CIRCULAR.]

HÆMOPHILIA is not very frequently met with in practice, more particularly in ear clinics, where it is only very exceptionally seen. To this circumstance is, no doubt, due the fact that altogether only three cases of this kind are published in the literature of the subject (Rohrer in 1899, Haug in 1893, and Ziem in 1855).

L., a boy, æt. 2½ months, fairly well developed, for two days had been restless, weeping continually, unable to sleep, with fever and pain in left ear. I first saw the little patient on January 25th, 1899. On examining him I found acute inflammation of the left middle ear. The auditory meatus, in view of the patient's age, was capacious, and presented nothing abnormal. The tympanic membrane was red and was bulged forwards. The malleus was not visible, and the pharyngo-nasal cavity appeared to be normal.

Considering the high fever (39.2°C.), and the restlessness of the child, I thought it imperative to perform paracentesis through the anterior lower part of the tympanic membrane, when a slight yellowish-red discharge escaped from the tympanic cavity. The treatment of the ear consisted in the removal of the discharge from the auditory meatus by wiping away with cotton, and in addition I ordered cold compresses to the mastoid process, merely by way of precaution, although it did not present any abnormal appearances, and no tenderness could be made out, although, as the child was continually weeping, one could not feel certain as to that.

The temperature fell on the following day and the child became quiet, the discharge, too, was only of a slight amount. On January 30th the discharge was very slight; the child had neither fever nor pain. The tympanic membrane was pale over a considerable area, so that I could use the Politzer bag.

The condition of the child improved from day to day, the discharge was small in quantity, and the tympanic membrane was normal in colour, and when performing the air-blowing the air passed freely through the ear.

On February 2nd I was urgently called to the patient, because since midnight there had been constant hæmorrhage from his ear. The whole auditory meatus was filled with fresh blood. This being syringed out, I could discover no cause for the bleeding, either in the auditory meatus, or on the tympanic membrane. The occurrence of the bleeding the more surprised me, for I had seen the patient on the previous day, and he was getting on very well, so that complete healing was to be expected within a few days.

I was now told by the parents that many persons of their family suffered from bleedings. One of the patient's brothers had bled profusely in consequence of a tooth extraction, and the hæmorrhage was arrested with difficulty. The parents gave me other information, from which I concluded that hæmophilia was prevalent in their family. There was no history of a blow or other injury subsequent to the operation to explain the occurrence of the hæmorrhage.

To arrest the hæmorrhage I plugged the auditory meatus with sterilised gauze, but this was soon soaked through, and bleeding continued. Later on I tried to plug the meatus, using a tampon of cotton steeped in a solution of alum, but this, too, became saturated with the profusely oozing blood. I tried hot and cold syringing but failed to attain my object.

On the fourth day the child's parents wished to consult Prof. Bokay, an old acquaintance of the family, who prescribed ergot internally.

In spite of all these treatments the bleeding lasted for eight days, so that we were already inclined to foretell a fatal issue. But fortunately, on the ninth day the bleeding ceased quite unexpectedly.

Throughout the whole duration of the hæmorrhage no blood had leaked into the Eustachian tube. On the sixth day I removed a small blood-clot from the auditory meatus in order to investigate it microscopically. The preparation showed pus-cells embedded in mucus.

After the cessation of the hæmorrhage improvement has speedily set in. The ear discharge entirely ceased, and the hole in the tympanic membrane has quite healed within four days. The child became quiet and slept well.

When I last saw the patient on February 28th the tympanic membrane looked quite normal, and the child was again vigorous and healthy as formerly.

A similar case of hæmophilic bleeding is reported by Haug.

It may not be superfluous to mention that in intra-tympanic operations performed by otologists similar hæmorrhages may occur as the result of injury to the carotid or to the internal jugular vein. Such bleedings can easily be mistaken for those of hæmophilic origin.

For example, Ludewig, Müller, and Hildebrandt have published cases in which the internal jugular vein had been injured during paracentesis, while Jacobi injured it when perforating the tympanic membrane by the aid of the galvano-cautery. The bleeding was arrested by plugging. However, in the case of Jacobi, pyæmic fever set in on the fourth day with formation of thrombi, and in consequence thereof the case ended fatally on the eighth day. Moor has described a profuse hæmorrhage also following injury of the vein inflicted during attempts to remove a foreign body from the tympanic cavity.

The carotid may also be injured, though this is very exceptional, when there is a congenital defect in the paper-thin anterior wall of the tympanic cavity. Such cases are described by Körner, Zaufal, Friedlovsky, Zuckerkandl. In all these cases the injury was due to paracentesis. The injury mostly occurs in cases where the carotid lies very much to one side, and in its course, having a partial broadening,

it forces the promontory backwards and upwards; to this it is added that the labyrinth wall (in its lower half), narrowing the tympanic cavity, comes unusually near to the tympanic membrane.

Under these circumstances it may happen that the pulsation of the carotid, which lies partly on the promontory, is conveyed to the cochlear nerve, giving rise to noises in an otherwise healthy ear.

Injury to the jugular vein, by reason of its anatomical and embryological relations, can occur very easily.

Usually the lower wall of the tympanic cavity separates the cavity from the internal jugular vein. But this wall varies considerably in thickness. Thus, according to Zaufal it is from one-quarter to one millimetre, and according to Merkel it is almost two millimetres thick. Sometimes it is only of the thickness of paper, and at other times it is more or less deficient, and in very rare instances it may even be totally absent, in which event the vein comes into direct contact with the mucous membrane of the tympanic cavity.

The defect can be variously explained. Thus it may be congenital, it may result from hindered development of the lower long wall of the cavity, or in consequence of defective ossification. The defect may, moreover, be due to excessive enlargement of the fossa jugularis. Senile atrophy, rachitis, and caries, too, may give rise to this anatomical abnormality of the lower wall of the tympanic cavity. These defects are mostly observable in skulls, which also present other anomalies and defects.

Although various theories have been advanced, the cause of hæmophilia is still far from settled. Anatomical examinations made up to the present are neither characteristic nor do they afford any positive results.

The first bleeding occurs, as a rule, previously to the end of the second year of life; only rarely it presents itself later on. Cases, however, are recorded in which hæmophilic bleeding has set in at the twenty-second year of life. As the age increases the hæmophilic tendency diminishes. The chief symptom of hæmophilia is profuse bleeding in the absence of any adequate cause, comparatively trifling solutions of continuity giving rise to relatively copious hæmorrhage. The blood oozes from the wound just as it does from a sponge which is saturated with blood. The bleeding lasts for hours intermittently, and no spouting arteries can ever be seen.

Small wounds bleed more freely than large ones. The other symptoms are familiar to every physician.

It is interesting to note, moreover, that in some cases the bleeding is preceded by parosmia (Eichhorl). For example, it is recorded that a certain patient had smelled, and another one had tasted, blood before the coming on of the bleeding.

The prognosis is anything but favourable.

In regard to treatment, it is advisable when bleeding occurs to apply hæmostatics, or the galvano-cautery. The local application of gelatine has done good service in some cases. Also injections of pilocarpine given hypodermically are found in some cases to have given satisfactory results. Ergot, or hydrastis canadensis, may be given internally and ligature of the carotid artery has more than once been resorted to.

The regimen and diet of the hæmophilic are points to which attention must be paid. Exciting and irritating foods and beverages must be avoided (wine, tea, coffee). Also it is important to strengthen the organism. Good feeding, milk cure, the using of baths, residence at the sea-side, &c., are very recommendable. Gymnastics and other sporting pastimes should not be allowed.

Transactions of Societies.

BRITISH GYNÆCOLOGICAL SOCIETY. MEETING HELD FEB. 13TH, 1902.

HALLIDAY CROOM, F.R.C.S.E., F.R.S.E., President, in the Chair.

DR. F. VINCENT RAMSAY showed a dilator which differed in one important particular from any of the various modifications of Hagar's at present in use. This instrument was virtually a hollow tube open at both ends in contradistinction to a tube closed at both ends to which the ordinary dilator might be likened. He pointed out that the dilators generally in use acted as pistons when pushed in through the cervical canal, the extent to which they did so depending on the tightness with which they were grasped by the cervix. In consequence of this piston action, when a dilator was introduced into the uterus resistance had to be overcome in addition to that offered by the tissues resisting dilatation, and deleterious matter was also liable to be forced from the interior of the uterus into the Fallopian tubes. He contended that dilatation of the cervix and curettage of the endometrium were liable to be followed by salpingitis of varying severity, even though the operation were performed under the most favourable circumstances, and every possible precaution had been taken. This he attributed to the disadvantages attending the use of the ordinary dilators, to obviate which he had had the instruments before the Society made by Messrs. Down Bros. There was a ridge on the under surface by means of which rotation could be prevented and the exact position of the instrument defined.

MR. R. O'CALLAGHAN showed sub-mucous and intra-ligamentary myomata removed, by abdominal section, from a woman, æt. 48. The patient had suffered for four years from continuous hæmorrhage, and yet had never been examined until presenting herself at the hospital. He endeavoured to remove the tumour by the vagina, but the small size of the latter rendered it impossible. He therefore removed it by the abdomen. The patient made an excellent recovery.

MR. O'CALLAGHAN also showed a uterus removed by abdominal hysterectomy for cancer of the cervix. The patient, æt. 84, had suffered for a year from an offensive discharge, and Mr. O'Callaghan believing the cervix to be carcinomatous, removed it, amputating it as high as possible. A pathological report, furnished by Mr. Targett, confirmed him in his unfavourable diagnosis, and he decided to remove the uterus and appendages. He adopted abdominal in preference to vaginal coliotomy because the left ovary was cystic and enlarged, both ovaries were adherent, and the patient had also old-standing salpingitis.

DR. MACNAUGHTON-JONES exhibited Professor Bossi's instrument for rapid dilatation of the cervix in cases of contracted pelvis and eclampsia, more especially the latter. By its means the cervical canal could be dilated up to from eight to ten centimetres in fifteen to twenty minutes. This dilator had now been used successfully in a large number of cases by Professor Bossi and by Drs. Paoli and Zirolla in his Klinik at Genoa. Dr. Macnaughton-Jones thought that it might be used with advantage also for dilating the cervix in inversion. He had first seen it used by Professor Leopold, of Dresden, prior to the operation of cephalotripsy in a case of rachitic pelvis.

DR. MACNAUGHTON-JONES then showed a powerful clamp used by Professor Zweifel in both abdominal and vaginal hysterectomy. It was not so cumbersome an instrument as Doyen's, and its shape rendered its application to the broad ligaments through the vagina very much easier. He had himself, when at Leipsic, had an opportunity of witnessing its efficiency in preventing hæmorrhage.

DR. HAYWOOD SMITH spoke highly of Doyen's pressure forceps, which he was in the habit of using; but he believed the instrument before the society would be very much more easily manipulated, especially in vaginal hysterectomy.

DR. MACNAUGHTON-JONES also showed a beautifully stained section of a carcinomatous uterus in an early stage of pregnancy. The section, which had been rendered transparent, embraced the entire uterus. The hypertrophied muscular tissue, the various portions of the decidua, the cavity of the amnion, and the contained embryo were easily differentiated. The specimen, which had been prepared in Professor Bumm's Klinik at Halle, had been hardened in picric acid, treated with alcohol, permeated with colloidin, and then cut with a large microtome and stained with carmine.

THE PRESIDENT then read his inaugural address, an abstract of which will be found on page 207.

DR. ROBERT BARNES, the Honorary President, proposed a vote of thanks to the President.

This was seconded by Dr. MANSSELL MOULLIN, and supported by Drs. WALLACE and HAYWOOD SMITH.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

MEETING AT THE ROYAL COLLEGE OF PHYSICIANS,
ON FRIDAY EVENING, FEB. 14TH, 1902.

DR. NINIAN FALKNER, President, in the Chair.

THE PRESIDENT in his opening address gave a summary of the work of the Section of State Medicine for the ten years during which he had acted as secretary. He then gave a short sketch of the birth and progress of the history of notification of diseases in England, and presented a summary of the notification of certain infectious diseases in the cities of Dublin and Belfast, and the urban district of Rathmines and the Pembroke urban district, as published in the weekly reports of the Registrar-General for the year 1901. The President having invited criticism on his address,

MR. D. E. FLINN expressed regret that some areas had not yet adopted the Notification Act. Had the statistics of the whole area been available for analysis, the address would have been even more valuable. In his experience rural councils were more readily impressed with the value of notification of infectious diseases than urban councils, who seemed to see nothing in the Act other than increased expenses.

DR. THOMAS DONNELLY thought the address was a very suggestive one. Sanitary authorities shrank from the expense of preventive measures because they failed to recognise that the expenditure on prevention is practically nothing to that which an epidemic would entail. An account of the relative proportion between morbidity and mortality in cases of infectious diseases would be highly interesting and very valuable. Registration is at present very accurately carried out, but he feared that a considerable percentage of infectious diseases are not notified; some, especially the medical officers of health, are very particular in notifying the diseases made compulsory, and many of them, like himself, voluntarily notify phthisis; as a rule, he finds the poor, once they know the object in notification, raise no objection to the carrying out of the Act.

DR. F. C. MARTLEY considered that one of the principal difficulties they have to contend with is the getting of statistics. By writing to the medical officers and other officials of English working class societies, he tried to learn something of the morbidity and mortality of such; but in some the lives were so carefully selected by the medical officers that the results were inconclusive.

DR. CRAIG felt that phthisis should be included in the list of infectious diseases to be notified to the Public Health authorities. Some years ago, some of the Corporation of Dublin officials gave him to understand that phthisis would be included, but it has not been. Many physicians notify the presence of the disease. But what good comes of it? Some leaflets are sent to the infected house, and a coat of whitewash is applied, and then everything relapses into its old dirty insanitary condition.

DR. KIRKPATRICK thought that the public ignorance of the infectious nature of the disease is largely due to hospital physicians putting phthisical patients into general wards. Seeing this, the public cannot believe the disease to be infectious.

Mr. H. G. CROLY said that if the members of the medical profession are convinced of one thing more than another, it is that phthisis is infectious. And one proof of the good such conviction does is the notice in tramscars prohibiting spitting—a habit begotten of laziness. He fully approves of phthisis being included in the list of notifiable diseases. How much better prevention is than cure, is well shown by the good results attending re-vaccinations during the epidemic of small-pox twenty years ago.

Mr. DOYLE would like to see syphilis included in the list of diseases to be notified—it is both contagious and infectious, and modifies all other diseases.

Dr. MAGENNIS said he had only one fault to find with Dr. Falkiner's address, and that was one not usually complained of by the critics of the papers of statisticians—his paper was too short. Every minute it was becoming more interesting, when he brought it too quickly to a close. He hoped Dr. Falkiner would continue to compile such statistics, as they would certainly benefit humanity and be helpful to sanitary reformers.

The PRESIDENT, in reply, said that phthisis was freely disseminated by patients in the last stage of the disease travelling about in public conveyances. Some years ago, in a paper read before this Section, he advocated the notification of primary syphilis. He would be glad to see the literature of the Tuberculosis Congress spread about. Medical men might give it a place on their waiting-room tables; the public must be educated to see the value of preventive medicine.

Mr. H. GRAY CROLY then read his paper,

DISPOSAL OF SURGICAL DRESSINGS AND OTHER REFUSE MATTER IN HOSPITALS.

He considered that of the many surgeons who take every care of the dressings that are being put on their patients a very small percentage ask what becomes of the used dressings. When many years ago he commenced practice, poultices, tow, and used dressings were too often shoved down the closet pan, and not unfrequently blocked the pipes. The closets were constantly being repaired. Then lady nurses took to stuffing them into unused corners until the morning cleaning came about, when they were carried off to the dust-bin, to ferment and rot until a scavenger carted them off. The dust-bin was better than the closet, and the Corporation bucket was better than the dust-bin, but it was far from being what it should be. Every used dressing ought to be put into a covered bucket and carried out of the ward to a furnace, a quick-burning furnace, and then and there be incinerated. Lieutenant-Colonel Backhouse informed him that in the military hospitals of Calcutta, Madras, and Bombay, all used dressings are placed in a pail which has a concave perforated lid covered with fresh carbon, and are at once carried out beyond the hospital grounds and burnt in a quick furnace. In the Rotunda Hospital and some others in this city the furnace is used, but it should be used in one and all of the hospitals. Aseptic wards are impossible if a rotting mass of dressings are lying for twenty-four hours awaiting removal by the Corporation dustman.

Mr. TOBIN considered Mr. Croly to be deserving of special thanks for his practical paper. Years ago, when he was in Netley, a farmer contracted for the hospital refuse, and utilised it as a top dressing for his land. On one occasion when hunting he was thrown in a field so manured, and fell into some of their old dressings. He asked could anything be more calculated to spread disease? There is but one way of disposing of used dressings—burning; all excreta, all used dressings should be removed from the ward without delay, and then burnt.

Dr. POTTER, as one of the visiting committee of the Dublin Hospital Sunday Fund, thought they could not be too thankful to Mr. Croly for the paper. Now that he came to consider the evils of dressings remaining for the dustman's visit, he could no longer certify such a method as satisfactory to his committee. He was, however, not inclined to send bandages to the destructor; he thought it should be possible to wash and sterilise them.

Mr. DOYLE did not think that modern used dressings were impregnated with infectious matter. Our wounds were aseptic, and there was no comparison between the modern dressing on its removal and that of the past; nevertheless, the Corporation dustbins were fruitful sources of disease, the lids were anything but close, and poor old women gathered round them raking their contents for cinders, and spreading such infection as they contained far and wide. Burning was not alone the best way, but was the only way of properly disposing of used dressings.

Dr. CRAIG highly approved of Mr. Croly's suggestion—it places the infected dressing beyond power of doing harm. There was no telling what might happen if used dressings were allowed to lie about. A used poultice that a careless nurse left lying in one of the wards in the Meath Hospital was eaten by a child patient. There was the further risk of flies carrying infection from them.

The PRESIDENT approved of Mr. Croly's suggestions. He thought the used dressings when in the bucket should be treated to a douche of sulphurous dioxide, which was now readily and cheaply obtainable. Of destructors, he looked on Scott's as the best; in half an hour you can get a heat of 400° F. The Section, he thought, must acknowledge that Mr. Croly, in his simple and practical paper, had made a valuable contribution to preventive medicine.

Mr. CROLY having replied, the meeting terminated.

DUBLIN SANITARY ASSOCIATION.

THE annual general meeting of the Dublin Sanitary Association was held on Thursday last. The President, Dr. Charles F. Moore, occupied the chair. The annual report stated that the Council during the past year had given considerable attention to the sanitary condition of, and overcrowding in, the National schools within the city. It was essential that National schools should be in the best possible sanitary condition. A large portion of last year's report was taken up by the subject of tuberculosis. This disease is very rife in Dublin, and is the cause, directly or indirectly, of a very large proportion of the deaths in this city. The Council were fully alive to the fact that general hospitals are not suitable as sanatoria for consumptives, but are of opinion that many cases are greatly benefited by a short stay in hospital while they are suffering from some temporary aggravation of their disease. The Council hoped that the Advisory Board appointed by his Majesty to deal with the munificent sum of £200,000 placed at his Majesty's disposal by Sir E. Cassel would see their way to recommend the allocation of a portion of that gift for the treatment of consumption in Ireland. The Council had been investigating the causes of the high infant mortality prevalent in the city, and were of opinion that "diet diseases" or food disorders, which cause high mortality, being preventable, directions for the proper arrangement and feeding of infants should be circulated amongst the community. Having referred to the improvement of tenement dwellings by the Corporation, the Council stated they drew the attention of the Local Government Board for Ireland to the eminently unsatisfactory state which notifications of infectious diseases at present stand in the Dublin Registration Area and adjoining districts and that the Notification of Infectious Diseases Act has not yet been adopted in such important urban districts as Kingstown, Blackrock, and Dalkey. The Council had frequently under their notice the prevalence of small-pox in England and Scotland, and the probability of its being introduced into Dublin, and they ventured to support the appeal made by Sir Charles Cameron in the public Press relative to vaccination and re-vaccination. The report also dealt with such matters as the proper classification of pneumonia, and the notification of infectious diseases.

Sir CHRISTOPHER NIXON, M.D., in moving the adoption of the report, said that at the last meeting of the College of Physicians the suggestion was approved to have a circular drafted giving instruction in the most popular way of the proper food suitable for children of certain age as to quantity and quality. As to the matter of notification of diseases, he could not under-

stand the absurd position taken up by Kingstown, Blackrock, and Dalkey. He quite agreed with the recommendation of the Council that it was quite time now that the law with regard to this matter should be assimilated to the law existing in England. He would also advocate the extension of the law generally as it exists in England and Scotland, especially as to the appointment of officers of health for certain areas who could give their entire time to the office. Dealing with the question of tuberculosis, he thought it had been shown that Professor Koch had not successfully proved that bovine tuberculosis was uncommunicable to man, and, that being the case, he quite endorsed the suggestion of the Association to take extreme care as to the class of milk supplied to their hospitals.

Dr. W. J. CHETWODE CRAWLEY seconded the motion, and the report was adopted.

The President then delivered his address, which dealt with the threatened visitation of a small-pox epidemic to this country, and in the course of an able speech said that the probable cause of much illness made it all the more necessary for the inhabitants of both islands to adopt vaccination and re-vaccination, and all other means of arming themselves against disease in every form. It was, he thought, to be regretted that the Government which passed the existing Vaccination Act did not see its way to pass a really useful Act, embodying not only compulsory vaccination, but also compulsory re-vaccination.

Professor M'WEENEY, in moving a vote of thanks to the President for his address, said that he regretted very much that the Local Government Act of 1898 did not make it possible to appoint medical officers of health whose whole time could be given to the duties of their office. Referring to the matter of tuberculosis, he considered that in Dublin there should be some control over the milk supply, and that samples of milk should be frequently taken and examined bacteriologically.

The motion was carried.

SIR CHARLES CAMERON, in moving the election of the members of the Council of the Association, said he agreed with what Dr. M'Weeney had said with regard to the system of bacteriological examination of milk in Dublin, and that the matter was at present under the consideration of the Public Health Committee. A report would soon be presented by that body to the City Council. With regard to the examination of milch cows he might say they had already appointed a very skilled veterinarian, whose duty was to see the udders of the cows, and refuse to pass those who showed symptoms of bovine tuberculosis.

The resolution was carried, and the meeting concluded.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, February 23rd, 1902.

A NOVEL POINT IN HEREDITY.

A CURIOUS point has been recently raised before the Civil Tribunal of the Seine. In January, 1901, a lady died after having given birth to an infant at the sixth month of gestation, which was reared for a month in a *convalescence*, when it, too, died. The question to be decided was whether an infant born at a period reputed to be non-viable could inherit, irrespective of a soon-to-be-extinguished vitality. At first sight the question seems simple enough, but evidently the tribunal thought otherwise, since it nominated a commission of experts to decide whether or not the infant presented the " requisite viability " to qualify as an heir.

A FATAL ENEMA.

THE administration of an enema is usually a simple and innocent operation, but that this is not invariably so is shown by the case published by Dr. Gross, a French practitioner. The patient was allowed to give the

injection to himself, and he complained at the time, that the introduction of the cannula caused pain. Later, he had a fairly copious motion mixed with blood, but the next day he was out of sorts and the temperature rose. A purgative was ordered but produced no effect, and on the third day the abdomen became tympanitic and there was frequent vomiting. Rectal examination revealed the presence of a large soft tumour to the left of the rectum, composed of sloughing tissues. The patient died soon after and the autopsy showed partial sloughing of the rectum with a large area of cellulitis. Medical literature contains some thirty instances of a similar kind, of which sixteen proved fatal. The moral is that even so simple an intervention as a clyster calls for care and gentleness.

COMPULSORY VACCINATION.

By the new sanitary regulations, which have just come into force in France, vaccination is made obligatory within the first year from birth, to be followed by revaccination at the ages of eleven and twenty-one.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, Feb. 22nd, 1902.

At the Society fur Innere Medizin Hr. Destzeich related a case of

CANCER OF THE ESOPHAGUS

arising from a chronic simple ulcer. The patient, *et.* 63, had long suffered from gastric disturbance. For the last six months emaciation and cachexia had advanced. For some time there was fever arising, as was later ascertained from a subphrenic abscess. The patient died, and the autopsy revealed an interesting condition. The *oesophagus*, on being opened, was found to be dilated gradually from above downwards, and was there contracted to a moderate stenosis. In the wide part was an ulcerated fungous cancerous growth pressing upon a round deep ulcer, above the edges of which the mucous membrane was in places drawn over. The history, the form of the ulcer, and the stenosis made it probable that a peptic ulcer formerly existed there, and that a carcinoma developed on it.

Hr. Jurgens showed

A RARE CASE OF AMOEBA DISEASE.

The speaker had already described a similar case in 1896; there the ulcers had perforated in the region of the ileo-cæcal valve, and had given rise to phlegmons on the skin, which had rendered operation necessary. Two categories of amoeba disease must be distinguished (1) primary (colitis diphtherica), such as was found in Asiatic dysentery. In the case of a soldier who had returned from the China war and died, the speaker had made an examination and found amoebæ in Lieberkuhn's follicles. The amoeba had caused ulcers with undermined edges. Even the external form of the ulcer was characteristic of amoeba invasion. (2) The secondary invasion in tuberculous enteritis. Here we had tuberculous peritonitis; on the inner surface of the intestine, however, there was no tubercle, but only amoebæ. Here possibly there were first tuberculous ulcers which had been invaded by amoebæ, whereby the tubercle was destroyed. Stenosis was also sometimes caused by the amoebæ, as was seen in one of the preparations.

At the Free Society of Surgeons, Hr. Frendenberg showed three cases in which

BOTTINI'S OPERATION

had been performed. The operation consists, as is known, in electrical cauterisation of the enlarged prostate. All three patients had been relieved of their troubles. The remarkable feature of the cases was the length of time during which the patients had been unable to empty the bladder. One patient had had complete retention of urine for ten years, the second for twenty-seven years, and both had been obliged during the whole of the time to empty the bladder by catheterisation, while the third case was remarkable from the fact that for four years and two months he had been perfectly well. In all the course after operation was undisturbed, but in the last case complete recovery did not take place until after the third operation. The delayed result in that case was due to an imperfect instrument, which had since been improved by the speaker. The retention of urine in prostatic hypertrophy was due to the prostate itself and not to the bladder.

Hr. Frank had met with a mishap in Bottini's operation, and believed it was due to the hypertrophy being towards the bulbous part of the urethra, and not towards the lumen of the bladder. In such cases the operation was unsuitable, and a prostatectomy was indicated.

Dr. Frendenburg, in reply to a question as to statistics, pointed to the cases published by himself in 1900. Since then he had operated in thirty-two cases with one death. In twenty-five the treatment was concluded. There were twenty recoveries, four improvements, and one failure. He considered cures as cures even when the urine was turbid this turbidity was often due to chronic pyelitis, and to expect to cure this by the operation was unreasonable. He did not agree with Frank in the least in his limits of indication for the operation.

Hr. Bauer then discussed

SOME TOXINES.

Bacteriological examination in septic diseases have during recent years given positive results with much greater frequency than had been expected, but the results as regarded importance in respect to prognosis had been overvalued. The occurrence of bacteria in the blood in infectious diseases, as well as in surgical infection, had not the significance formerly attributed to it. The questions pertaining to this should be tested experimentally. There were difficulties in the way of this, as in experimenting with strepto and staphylococci there was no standard of virulence; these developed their toxins—and in this they differ, for example, from diphtheria—first during growth on a living nutrient soil, and it was therefore extraordinarily difficult to determine a toxine unit.

The grave symptoms accompanying sepsis might arise from living or dead bacteria, or, finally, from the toxins formed at the infested spot.

As regarded the conditions of growth of the serum on blood, whether human or animal blood, the conditions were most favourable when a little grape sugar was added and the nutrient soil was kept fluid.

If he inoculated animals with strepto or staphylococci there were endlessly more germs in the blood than were ever found in human blood; if he inoculated them with the quantities here found the animals were made temporarily ill, but they recovered.

Dead bacteria were useless for experiment. In order to obtain the toxine found at the infected spot he took some tissue from the infected part, dried it in the exsiccator, and pulverised it. Chloroform was then poured over it ten to twelve times in order to kill any living germs, it was then washed and filtered through a clay cylinder. The filtrate must contain all the toxins. If some of this was injected a local swelling arose with fever, but it soon disappeared. If, however, along with this a very small quantity of virulent germs were injected, so small that injected alone they would set up no serious condition, then a progressing phlegmon was started, ending in death, with symptoms of sepsis.

If the local poison material was admitted directly into the blood current it alone caused death with septic symptoms.

If cocci were subcutaneously injected alone no bacteria were found locally, for the first few hours, but if a very small quantity of local poison was introduced into the blood tracts, in from thirty to forty minutes thousands of bacteria were found in the blood. He thought from the large number of germs in the blood that this must have before contained bacteria which increased in this immeasurable manner from the moment of the introduction of the poison. He looked upon the bacteria in the blood only as a symptom which was to be considered as the measure of the action of the local toxins. Treatment must therefore be directed to this, we must endeavour to destroy these. He thought electrolysis would be useful if a suitable armamentarium could be devised.

In any case, in all septic diseases energetic local treatment was indicated, and in case of new amputations was justifiable.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, Feb. 22nd, 1902.

PROPHYLAXIS OF TUBERCULOSIS.

Koch wished to state before Weichselbaum commenced his prophylaxis that he did not agree with Klebs with respect to primary tuberculosis in the bowel being a very rare disease. If the statistics of *tabes mesenterica* be of any value, which they ought to be, 25 per cent. of the deaths occurring among children are due to tubercle of the bowel, which is acknowledged by Hnepppe as abdominal primary tuberculosis.

As to the transmission of tuberculosis from cattle to man, it is acknowledged that "Perlsucht" material, when brought into contact with cuts in the hands of attendants, produces tuberculous sores on the hands, arms, &c., with lupus in many cases, which may not be identical, but must be very closely connected, though still an open question.

It has also been stated that the poison passes from the bronchial glands to the lungs, but if closely followed it will be found that many of the lungs have been infected long before the bronchial glands.

According to Cornet and Flugge two primary modes are open for the introduction of the poison, viz., by small particles of dust in the air, which carry the germ into the lung (Cornet), or secondly, fine particles of fluid

air borne from coughing, which may be carried by the healthy into the lung (Flügge).

As to the disposition of the lung apex being more susceptible, many theories have been advanced. B. Hirschfeld locates the point to the posterior bronchus at the apex becoming more crooked, and therefore it retains the fine particles after they have once entered where the microbe subsequently germinates.

Schmarl has another cause for this retention in the apex, which he considers is due to a constitutional angular bending of the first rib, whereby the lung is turned sharply forward at the apex and pressed into a fork shape, which entangles the germ in the same manner as that affirmed by Hirschfeld.

Freund goes further, and tells us that the bending of the first rib takes place in the articular cartilage which is congenital. This congenital defect can be overcome by exercise, which puts a strain on the elevation, and produces a pseudo-arthritis of the manubrial connection. To prove the presence of tuberculosis it is not sufficient to diagnose "Säurefester" bacilli, but the anatomical, physiological and histological changes must be proved.

Weichselbaum said tuberculosis was sadly neglected in Vienna, and Austria in general. Such apathy was allowing the disease to increase, while scepticism in the contagion of the disease was still entertained. Every civilised state with the exception of Turkey had now made some effort to allay or ameliorate the disease. The most effectual method to deal with this would be central stations for examination and testing of suspected cases throughout the country. Such centres for diagnosis should be in possession of the latest methods of differentiation of the real bacilli and the "Säurefester" bacilli in the different secretions. To eliminate all doubt animal experiments and tuberculin would be absolutely necessary. The sero-diagnosis and agglutination tests are yet very vague to have any diagnostic value. In addition to this, the inhabitants should be instructed by advertisements and otherwise the need of precaution, and public institutions provided for the proper treatment of the disease.

How far "Perlsucht" can be transmitted in the human being is very difficult to say yet, but the bacilli of human tuberculosis will suffer, no doubt, in its transmission through the sputum either moist or dry. Such excreta would require to be destroyed. Fine handkerchiefs of Japanese paper are the cheapest and handiest things for the sputum, which can be burned, according to Flügge. Schrotter proposes spittoons of the same fabric that could be burned after use, while Kornfeld suggests the use of asbestos that could be burned and cleaned. In public places such utensils should be plentiful and within easy reach. Disinfection of the body, furniture, and bedding should be carefully observed. Isolation of severe cases would be the most effectual way of dealing with the disease, but where it is light the patient ought to be taught and warned to protect others.

Whether Koch is right or not in affirming that "Perlsucht" can be transmitted to man we should use such precaution as if it were transmissible, and use the tuberculin test as standard, or boil the milk. Butter should only be made from Pasteurised cream. Tuberculin injections applied in doubtful cases, and the animals killed. Notification is a necessary adjunct to

guide the central authority to take the necessary precautions against infection. In cases of parental infection the children should be sent to boarding schools or isolated in some way to overcome the hereditary susceptibility and obviate the transmission of the disease as far as possible, from inhalation or possible admission by food at home.

TREATMENT OF TUBERCULOSIS BY BLUE LIGHT.

Kaiser gave his experience of the treatment of tuberculosis by blue rays. The quality of the light was taken from the blue spectrum line of the solar analysis, with 32 candle power, and at a distance of 20 centimetres, or 7.88 inches. He used it on a tuberculous sore on his own hand that he had vainly laboured for two years to heal, which closed within two months after commencing the treatment. He showed other two cases of pulmonary tuberculosis with most favourable results.

He concludes that the blue light acts adversely on the tuberculous bacilli, either inhibiting or killing the germs. He thinks the action of heat may be excluded in our estimate of the efficacy. That the real effect depends on the distance and intensity of the light; that the blue rays alone penetrate the body and thus affect the bacilli; that the rays act as an absorbent, and that they still pain by their anæsthetic action.

Continental Notes.

THE RIVIERA IN WINTER, 1902.

[FROM OUR OWN CORRESPONDENT.]

To anyone accustomed to spend a part or the whole of the winter months in "The Sunny South," the change of sequence in the usual order of visitors this season appears somewhat unaccountable. That fashion changes in respect to localities as well as in dress is everywhere self-evident; and that Egypt has attracted many (since the sanitary condition of that country has been under British control) who previously came here may account for a percentage of the loss of English visitors. That other factors are at work cannot, however be denied, and it has occurred to my mind when endeavouring to solve the enigma, whether the "Mentone Manifesto" against consumptives and the variola rumour concerning Nice, industriously circulated by certain rival health resorts, are not mainly responsible for the present paucity. Whatever its cause one is struck by the absence of the typical invalid along the shores of the Mediterranean from Hyères on the French coast to Allassio on the Italian side, and with them the necessary concomitants—their relatives and friends. That ill-advised "boycott" of the Mentone hotel proprietors is probably meeting the fate it deserved, as the medical profession could scarcely be expected to send patients to localities where they were unwelcome, and their friends would, of course, go with them elsewhere. If this absence of visitors were noticeable in Mentone alone it would create no surprise, but the whole Riviera has been suffering in like manner, and one sympathises with the hotel proprietors of Hyères, Cannes, Nice, Grasse, San Remo, &c., where English visitors (whether invalids or not) have been specially catered for in the past, and who are now suffering alike with the aggressors. The paucity of American visitors is also a feature this year; these, it is reported

have deferred their visit to Europe until the Coronation of King Edward. The fiction of small-pox at Nice has, however, been removed, and that town is filling at last. Medical men at home may now safely advise their patients and friends that the entire Littoral is free of epidemics, and that English visitors will be welcomed as of yore.

The Operating Theatres.

ROYAL FREE HOSPITAL.

OPERATION FOR CHRONIC OTITIS MEDIA WITH SUPRACRANIAL COMPLICATIONS OF AN UNUSUAL CHARACTER.—Mr. ROUGHTON operated on a girl, *æt.* 7, who had had a discharge from the left ear for three years; she had suffered from pain for two days before entering the hospital. Her condition on admission was: Temperature 102° ; she was complaining of pain in the ear and towards the back of the head, but there were no other symptoms pointing towards anything definite, but there was a slight tenderness over the mastoid, and a little fulness under the extreme upper part of sternomastoid muscle. At first Mr. Roughton formed the opinion that the case was one of Bezold's mastoiditis, that is to say, inflammation and suppuration extending to the apical mastoid cell and perforating towards the digastric fossa; he therefore determined to open up the mastoid process; on doing this he found the process inflamed, but there was no collection of pus. The symptoms he considered were not sufficiently definite to warrant opening the cranial cavity. No improvement, however, followed this operation, the temperature remained high, and the child gradually relapsed into a semi-comatose condition, but did not develop any symptoms pointing definitely to any of the well-known complications of middle ear disease. Forty-eight hours after the first operation the patient's condition was so much worse that Mr. Roughton decided to make a more thorough exploration. He reopened the wound and explored the lateral sinus, which he found normal. He then trephined an inch and a quarter above and behind the external auditory meatus, and exposed the temporo-sphenoidal lobe; the pulsation of the brain was almost entirely absent. A trocar was introduced into the brain in several directions with a negative result; he then explored the upper surface of the petrous portion of the temporal bone, but again with a negative result. Mr. Roughton said that the case was an extremely obscure one. It was obvious that there was no involvement of the lateral sinus; the exploration of the temporo-sphenoidal lobe seemed to negative the possibility of an abscess in that situation, and exploration of the upper surface of the petrous portion of the temporal bone showed that there was no extension of disease through the tegmen of the antrum or tympanum. He considered it useless to explore the cerebellum, as there was complete absence of all symptoms which one is accustomed to associate with cerebellar abscess. He thought the prognosis extremely grave. No improvement followed the last operation, the coma deepened, and the child died the next day.

At the post-mortem the only condition found was a diffuse meningitis affecting the base of the brain in the posterior fossa; there was no cerebral abscess, and no disease of the lateral sinus. It was obvious that no

operative measure could have saved the child's life. Mr. Roughton regarded the case as one of extension of disease from the middle ear to the posterior fossa of the skull by means of the lymphatic or venous systems. In such cases, he pointed out, it is common to find either thrombosis of the lateral sinus or a subdural collection of pus; both these conditions in this case were conspicuous by their absence. There was no evidence of tuberculosis at the autopsy.

FRENCH HOSPITAL AND DISPENSARY.

ABDOMINAL HYSTERECTOMY FOR LARGE SUB-MUCOUS MYOMA OF THE UTERUS, COMPLICATED BY INTRA-LIGAMENTOUS FIBROID.—Mr. O'CALLAGHAN operated on a woman, *æt.* 48, who had been bleeding for four years without intermission, and, strange to say, she had never been examined until she came to the out-patient department of the French Hospital, although blanched and presenting the marked appearance of a patient constantly losing blood. On admission a large sub-mucous myoma, the size of a cocoanut, was discovered filling up the uterus and presenting at the os. It was thought that it might be possible to remove this growth *per vaginam* by morcellation, but owing to a hard mass in the left broad ligament the uterus was very high up and immovable, the vagina also being small. It was decided therefore to remove the uterus through the abdominal wall. The usual incision was made and the ovarian and uterine vessels tied on the right side, but on the left was found another large fibroid opening up the broad ligament, which made it difficult to tie the vessel on that side, so it was necessary to amputate the uterus with the large submucous myoma first and then enucleate the intra-ligamentous one. There was a great deal of bleeding from the bed of this last tumour, and the difficulty was to find the source of this hæmorrhage, as Mr. O'Callaghan pointed out ligatures cannot be tied promiscuously round these parts; therefore, the cautery had to be applied pretty freely, this being effectual in arresting the bleeding. A gauze drain was passed through the vagina, and the peritoneal vault closed over the stump of the uterus and the cavity in the broad ligaments. The abdominal parietes were closed in two layers, the peritoneum by catgut and the muscles and skin by silkworm gut. Mr. O'Callaghan said one of the most interesting points about the case was that it was evidently possible for a woman to live in this country with a continuous hæmorrhage *per vaginam* without treatment or even examination, and to arrive at a stage where the bleeding would soon have brought about fatal consequences. The complication of the intra-ligamentous fibroid, he remarked, made the operation difficult, and the final stages very tedious.

Four weeks after operation the patient, having made an unexpectedly rapid convalescence, was sent to the French Hospital Convalescent Home at Brighton.

Medical and Clerical Remuneration.

In the Stow Union the salary paid to the workhouse chaplain is £20 in excess of that paid to the medical officer, and this circumstance raises the question—not which ministrations are most valuable, but which are most appreciated by the recipients. We make bold to say that were it put to the vote of the inmates the doctor would carry the day.

WEDNESDAY, FEBRUARY 26, 1902.

THE TUBERCULOSIS COMMISSION AT WORK.

HAPPILY the bombshell exploded by Professor Koch at the recent British Congress on Tuberculosis has had an excellent effect in stimulating research in all parts of the world. In the United Kingdom the spirit of enlightened curiosity aroused among the general public has led to a notable increase in sanatoria and to a wide diffusion of special knowledge among all ranks of the community. A Royal Commission has been appointed to carry out experimental research upon tuberculosis, especially as to the relationship, if any, between the disease in mankind and that in the lower animals. Sir Michael Foster, readers may be reminded, occupies the chair, where he is assisted by Professors Sims Woodhead, Sidney Martin, Boyce, and Dr. Steegman. In such hands the issue may be left with entire confidence as to securing the best result attainable in our present state of knowledge. To say that their work is momentous and epoch-making is to state the matter mildly. On their decision rests the future treatment of the meat supply of the nation, to say nothing of milk, for the control of meat must clearly be determined in practice by the finding of the Commission as to the identity or otherwise and the capability of mutual interchange of infection between the tubercle of man and of the lower animals. The Commissioners have not been wholly equipped by the State, but their wants have been partly supplied by the munificence of a private citizen—namely, Sir James Blyth, who with characteristic generosity has placed two model farms at Stanstead, Essex, at the disposal of the Commission. The necessary bacteriological and other buildings are being rapidly erected, and will soon be ready for the elaborate scheme of investigation which has been promulgated, and which will probably extend over the next five years. The cost of apparatus and, so to speak, of the stock-in-trade

of the Commission, together with salaries and other expenses, will naturally be covered by Government grants. The contribution by Sir James Blyth is, nevertheless, substantial to a degree, and well worthy of the best traditions of British citizenship. So far as any national distinction can be conferred in recognition of such distinguished service it has certainly been earned by Sir James Blyth. Many a peerage has been bestowed upon individuals whose claims, so far as public weal is concerned, have had little or no justification. It is quite likely, however, that titular distinctions of the kind in question offer no attraction to so modest a philanthropist as Sir James Blyth. The Commission to which he has extended his hospitality was founded for experimental rather than for curative experiments. Its existence was rendered absolutely necessary as a logical step in determining the scope of preventive measures in dealing with human tuberculosis. The experiments at the Stanstead farms will be conducted upon monkeys, guinea-pigs, rabbits, calves and cows a fact that will doubtless awake the easily excited echoes of the anti-vivisectionist stronghold. Men of science, however, can afford to treat sentimental folly of that kind with contempt. The supreme end and aim of modern medical science is to preserve as far as may be the life of man from the ravages of accident and of disease. If the life of the lower animals is necessary to the testing of facts essential to the complete knowledge of diseased processes in man, and in that way to their cure, then he does not for a moment hesitate to sacrifice the interests of the lower to those of the higher animal. In his eyes the life of man is sacred above all things, and that of the lower animals subordinate for purposes of experimental science, as it is universally assumed to be for purposes of food, clothing, sport, or personal ornament. Moreover, those who profess to attach so vast an importance to the interests of the lower animals may rest assured that the Stanstead experiments will contribute many facts of value in the cure and prevention of tuberculosis among cattle and other domestic animals. The effectual prevention of tuberculosis is one of the most attractive prospects that could be offered to the imagination of the ardent sanitarian. A generation ago, the mention of a scheme to secure such an end would have stamped the man that made the proposal as dwelling outside the range of practical social politics. Yet the impossibility of twenty years ago will doubtless be more or less the accomplished fact of twenty years hence. One of the first points to be settled is whether milk conveys the infection of tubercle from cows to man, because, as everyone knows, the brunt of an enormous mortality falls upon the children under five years of age, that is to say, upon that portion of the community in which milk forms a main article of diet. There is still a great deal to be done in enforcing purity of standard in the food supplies of the population of the United Kingdom. In hardly any single article is it more absolutely necessary in the interests of the public

health to enforce a stringent and rational control than in the case of milk. Whatever the result of the Stanstead researches may be as regards that particular food-stuff, it cannot fail to leave a lasting mark in the literature of tuberculosis, and to serve as a stimulus to the future prosecution of scientific research, whether supported by the State or by private bounty, both in our own and in other countries.

SURGERY OF THE HEART.

THE progress of surgery is nowhere more seen than in the operative treatment of wounds of the heart. Within the past few years it has furnished the text for several monographs on the Continent (a). At the beginning of the eighteenth century the medical profession and the public looked on wounds of the heart as incurable—in no way amenable to treatment. No attempt was made to treat the wound, although it was well known from experience in the past that the heart tolerated handling, and that wounds of the heart had healed. Latour reported the case of a soldier from whose heart a bullet was extracted six years after he was wounded; and still earlier Searle had shown that puncture of the heart was, under certain circumstances, a justifiable operation. Randall, of Tennessee, reported the case of a negro boy who was wounded by the discharge of a fowling-piece, in whom, sixty-seven days afterwards, an autopsy revealed three cicatrised wounds in the right ventricle, and two in the right auricle. One of the early numbers of the *Lancet* contains Bougon's case, in which the patient died from other causes and the heart wound was found cicatrised. Withal surgeons had not the boldness to expose the viscus and suture the wound. As late as February, 1830, Baron Dupuytren and his colleagues looked impotently on as the Duc de Berry bled to death from a heart wound, no more capable of dealing with the injury than were their predecessors with those of Henry IV. or William the Silent. How long surgeons might have remained content to look on as helpless speculators it is idle to speculate. They fully recognised the risks of interference, not the least of which was subsequent pericarditis, but they did not see their way to overcome them. In 1873 Mr. Calender's successful removal of a pin from the heart of one of his patients was as the letting in of light on the doubts and fears of the profession; and when, ten years afterwards, Block's paper, "Wounds of the Heart and their Treatment by Suture," was read at the German Surgical Congress it excited much interest, even though his data were solely from experiments on the lower animals. It is but fair to our predecessors to say that until we learned the value of asepsis no advance was made in the direction of direct operative interference with the heart, and, indeed, we may add, none would have been justifiable. As late as 1888 we find Mos-

cow's successful case of operation on the heart was followed by a severe attack of pericarditis and a tedious recovery, and in that case the tumultuous action of the heart, which makes suturing so difficult, was well marked. To-day the question that the surgeon will be called on to decide is, what class of cases justify operation and when should the operation be performed. The most favourable cases are those of simple stabs through the wall of one of the ventricles, uncomplicated with injury of the coronary vessels. Wounds of the auricles are so quickly fatal, as a rule, that they scarcely admit of operation. Besides, they contract so suddenly that the suturing of a wound of any other part than the auricle demands great dexterity; on the other hand, the wall of the chamber is so thin that it is more readily perforated than is that of the ventricle. The diagnosis is not always easy. Bech's maniac stabbed his heart five times with a fine stilet, and the wounds were not suspected during life, and were discovered five weeks after their infliction by an autopsy. The suicide of Cours wounded her superior vena cava, from which she bled to death into the pericardial sac, with all the clinical symptoms of a fatal heart wound. When to operate? The consensus of medical opinion seems to favour the postponement of the operation until the patient has recovered from the shock. Patients that survive the shock and the first great loss of blood offer the most hopeful cases. The extent and position of the wound cannot, however, be decided from the prolongation of the patient's life; in the Greenock case, 1819, the murdered man had his auricles and the aorta at its origin shattered to pieces, yet he walked some twenty feet before he fell, and he survived some little time. So far as we have been able to discover, some eighty odd operations have been performed on the heart, and of these thirty-four made a recovery, or at least survived the operation for some time; perhaps twenty made a complete recovery. The statistics are not encouraging in this class of injuries more than in others. At first operative interference has a high mortality in all classes of cases. But in time, when the technique of the operation improves, when its dangers are better understood, the percentage of recoveries rises. Ovariectomy took one hundred years to secure its present position as a justifiable and safe operation, and it won its position by the aid of anæsthetics and asepsis. Of the twenty successful cases of heart surgery it may safely be said that they were twenty lives saved from impending death. Of the technique of the operation little can be said, for it must be dependent on the extent of the wound and its complications. In some cases the external injury has been so extensive as to lay bare the heart; in others, as in the Sardinian case, it may call for the closest scrutiny to detect it. On the whole, we think no surgeon in the future would be justified in not attempting to suture a ventricular wound if the case was otherwise favourable for operation.

POOR-LAW MEDICAL SERVICE IN IRELAND.

It is doubtful whether medical men in England ever recognise the many extraordinary difficulties under which their brethren in Ireland labour. The manner in which appointments are made, the conditions which are in some cases attached to them, and the entire lack of compensation for putting up with such indignities, are sufficient to make one wonder what misfortunes have overwhelmed the candidates for Irish dispensaries to induce them to apply for such posts. Recently, two medical officers were appointed for a district in the north of Ireland, where the desire of reviving the Gaelic language was rampant. They were told that as they were ignorant of that language they would have to learn it, and were directed to present themselves for examination before the Board at a specified date. When the time came for the examination, the medical officers demanded their travelling expenses, and as the Board did not fall in with this suggestion, the proposed examination was allowed to lapse. Perhaps the most extraordinary and audacious attempt which has yet been made in Ireland to convert a medical man into a political partisan was attempted last week at Loughglynn, Co. Roscommon. A conference of tenants was held to protest against the payment of rent, and as Dr. M'Dermott, the dispensary medical officer, had paid his rent, the conference, presided over by the vice-chairman of the Roscommon County Council, declared Dr. M'Dermott's post vacant and ordered advertisements to be issued for another medical officer. It yet remains to be seen whether the Board of Guardians will obey their potential masters, and, if so, whether the Irish Local Government Board will meekly submit. If they do, we shall use every effort in our power to prevent a medical man applying for the post, and we fancy that the Irish Medical Corporations and medical bodies generally will do the same, and that other medical journals will assist. It is quite time for the medical profession to state definitely that its members, individually or as a body, will not allow the Poor-law Medical Service to be debased into a mere appendage of a political party. The Irish Poor-law Service was instituted for the relief of the sick, and not for the purpose of bestowing the political powers of patronage on rural nobodies. We regard the matter from no political point of view. Whether the Irish Nationalists, or the Irish Unionists, are affected by what we say does not concern us in the least, for, as a medical journal, we hold no political opinions. The medical man who gains the votes of an Orange lodge by professing to have been an Orangeman since he reached years of discretion, or the medical man who gains the votes of a Nationalist association by professing to have been a member of the National League since its inception, are alike bringing discredit on themselves, and lowering the status of the profession to which they belong. If the medical profession in Ireland is in danger of being reduced to the posi-

tion of a political appendage owing to the insistence of one party and the neglect of another, so that a medical man is in danger of losing his appointment because he fulfils his legal obligations, it is time for an outspoken protest to be made. It is time for the medical profession to state definitely that they will not allow their individual members to be turned into political counters.

Notes on Current Topics.

The Government and the Conscientious Objector.

VERILY theory and practice are far asunder as the poles, not only among the minnows but also at times among the Tritons. Mr. Balfour's Government, in their wisdom, reversed the beneficial policy of compulsory vaccination that had worked wonders in ridding the United Kingdom of a loathsome malady. Contrary to all established doctrines of legislation they decided that in this particular case the subject was to decide for himself whether he approved of the law and whether he would or would not submit himself and his children to vaccination. In the teeth of what would have seemed insuperable obstacles to any conservative upholder of the principles of statute law the "conscientious objector" was brought upon the scene. A few years later the invasion of the metropolis by a serious epidemic of small-pox has created the "conscientious assenter" to vaccination, who will in all likelihood outweigh the voting power of the small anti-vaccinationist sect at the next general election. The irony of the situation is shown in an amusing manner by the attitude of members of the Government, who describe grandiloquently to the Houses of Parliament the stringency and breadth of the measures they have adopted to combat the disease. Thus, Mr. Brodrick has announced to the civil servants of the War Office that any such person who declines to be vaccinated will have his or her pay stopped if absent owing to an attack of the disease. The Lord Chancellor has practically compelled all the officials in the Law Courts to be vaccinated. Why should not conscientious objectors be permitted in the Law Courts and in the War Office as well as elsewhere? We pause for a reply.

Latent Fracture of the Spine.

THE sequel to a most curious and ill-explained case of supposed latent fracture of the spine, to which we have already referred in these columns (Aug. 7th, 1901), occurred on Wednesday last in the Dublin Law Courts. As may be remembered, a chemist of the name of Murray fell down the stairs of a cellar and hurt his ankle. The apparent injury was not severe, and Mr. Murray was able to ride a bicycle to the Meath Hospital. He was also able to get in and out of a car. In the evening he complained of pain in his back, and in the morning he was found in his bed, dead. At the post-mortem examination a fracture of the left articular process of the fourth cervical vertebra was found, accompanied by extra-dural

effusion. Death was attributed to the pressure on the cord of the extravasated blood, and the coroner's jury found a verdict in accordance with this evidence. The sequel of the case was due to the fact that the deceased was insured in an accident insurance company, and that the company disputed the claim on the ground that the movements of the patient rendered it impossible that death could be due to fracture of the spinal column. The case was heard before the Master of the Rolls, and after medical evidence had been given on both sides, judgment was given in favour of the representatives of Mr. Murray. The case all through was a most puzzling one, but we do not think that on the medical evidence any other judgment was possible. The evidence went to prove that a fracture of the spine was present, that such a fracture could cause death, and that even though the usual symptoms of a cervical fracture were absent so was also any other discoverable cause of death. It is a case well worthy of being recorded in full.

Post-Mortem Examinations in Medico-Legal Cases.

THE young medical man can be called upon to perform few duties which cause so great a degree of trepidation as that of performing a post-mortem examination in cases of death from doubtful causes, or under suspicious circumstances. Those who have least fear are usually those who enjoy a pathologically high opinion of their own knowledge. It is especially perplexing for the tyro when he is called upon to make an examination in a case of suspected poisoning, unless he has a clear conception of the duties of an analyst. According to Dr. Harvey Littlejohn (a) there are four most important points, no matter how obvious the cause of death may be. First, in all medico-legal cases, examine every organ carefully. Secondly, in cases of suspected poisoning, after ligation and isolation, the stomach and intestines must be opened immediately in order to observe the condition of the mucous membrane as soon after death as possible. The entire contents must of course be saved and placed in a clean vessel, with the viscus which contained them, the vessel sealed, no preservative being added. If one must be added it should be alcohol, a specimen of which should be placed in another clean vessel and also sealed. Thirdly, the minimum of what should be removed and placed in separate bottles, securely sealed, labelled and initialled by the medical examiner, are:—I. the stomach and contents; II. the intestines and contents; III. half the liver with gall-bladder intact and its duct ligatured; IV. the spleen; V. a kidney; VI. the urine; VII. six ounces of blood. Fourthly, these articles should be kept in the custody of the medical examiner till he has handed them over to that of a duly authorised person, from whom he should obtain a detailed receipt stating that the seals are intact.

Small-pox Insurance.

EVEN so grim a subject as a wholesale outbreak of small-pox in crowded London is not without its humours. A few months ago some genius hit upon the happy idea of insuring himself against small-pox, and he accordingly secured a policy to that effect at Lloyd's, the great Exchange association where almost any risk upon earth may be covered by an insurance premium. With the growth of the epidemic the fashion for insurance against small-pox has increased until the craze has reached panic-stricken proportions. Instead of the modest £100 or £200 that represented the first ventures, policies of £500 and £1,000 are now plentiful as blackberries, while a number of people have insured for £5,000 in the event of their contracting the disease, and one gentleman has secured himself to the extent of £10,000. During the last week or two the rush of customers for small-pox insurances has been so great as seriously to interfere with the ordinary business at Lloyd's, and the underwriters have made a rule that henceforth all applications must be in writing and not by personal call. It is said that in a single week recently the small-pox policies taken out represented something like £250,000. Should any of the insured be attacked with modified small-pox it is interesting to speculate on the fierce conflict, medical and legal, that would probably be stirred up in the law courts. The extension of this branch of insurance work at Lloyd's to other diseases would open up an immense field of operations. Take the single malady of diphtheria. Many anxious parents would readily insure their offspring against the chances of that terrible disorder.

The Manual Induction of Anæsthesia in Java.

DR. M. L. STEINER relates in a German periodical a curious method by which Javanese medicine men induce general anæsthesia without the aid of any sort of drug. The anæsthetist, seated on the ground behind the patient, grasps the neck of the latter with both hands, pressing the index and middle fingers deeply in below the angle of the lower jaw until he reaches what they call the "Soporific Vessel," which he compresses strongly against the vertebral column. The patient, after a little time, begins to breathe more rapidly and more deeply and soon the head falls back, he being totally unconscious. As soon as the grasp is relaxed he regains consciousness and looks round with the surprise with which one is familiar in patients recovering from nitrous oxide. Dr. Steiner practised the method himself with considerable success but he found it easier to get at the internal carotid artery, this being the vessel aimed at, from the front. It is highly improbable that insensibility is induced merely by the pressure on the carotid. To begin with, this vessel cannot well be compressed without, at the same time obstructing the jugular vein, and there is reason to suspect that the compression of the pneumogastric nerve and certain sympathetic

(a) *Quarterly Medical Journal for Yorkshire*, February.

ganglia may also play a part in the production of unconsciousness. The ease with which anæsthesia can thus be induced, and the apparent innocuousness of the method, suggests that it may possibly be found applicable for operations of short duration. It would, however, be a curious irony if we should ultimately adopt a method practised by the ignorant and uncivilised inhabitants of this distant corner of the earth.

A Pill for the Anti-Vaccinationists.

DR. HARLEY BROOKS, the Medical Superintendent of the Mile End Infirmary, writes to the *Times* confirming the previously published statement that twenty-nine out of forty nurses actually on duty, who were revaccinated at periods of from one day to two years prior to the outbreak, have remained immune against small-pox. Four others were revaccinated immediately after the outbreak, two of them proving insusceptible, and these also have escaped infection. Three nurses had not been revaccinated, and they all caught the disease, as did four others who were revaccinated within the incubation period. To clinch matters, he adds that the steward, who was revaccinated, escaped, while his clerk, who eluded revaccination, was stricken down. If statistics such as these do not carry conviction the attempt to influence conduct by reason must be abandoned. At the same time it strikes one as singular that in an infirmary where the nurses and other employés are necessarily frequently exposed to infection any of them should have been permitted to remain unvaccinated. This fact may be likened to the straw in that it shows how the wind blows in Poor-law circles. Further light is thrown on this point by the grave indictment which the Vicar of St. Saviour's, Poplar, has brought against the Poplar Board of Guardians in respect of the resistance which they have persistently offered to his endeavours to facilitate the vaccination of the poor by opening a vaccination station in a room which he offered to place at their disposal. It is abundantly manifest that no future vaccination legislation will be worthy of commendation unless the administration of this branch of public health be taken out of the hands of these ill-informed and stiff-necked officials.

Early "Pestblatter."

THE January number of the *Library*, an extremely scholarly and artistic publication, contains *inter alia* some interesting reminiscences of the plague, pictorially illustrated by ancient engravings, between the years 1347 and 1500. The latter half of that period coincides with the rise of engraving, both on copper and on wood, and wood engraving, the more popular branch of the graphic arts, reflects with wonderful completeness, considering the scarcity of extant prints, the habits and modes of thought of the people who patronised it. Scientific remedies, so far at least as our documents go, were little in demand. There are three type-printed broadsides which recommend a certain regimen in time of plague, but only one

attempts to prescribe for a patient actually infected. The leading idea was that the Deity sent pestilence as a visitation for sin, much in the same light as it is at present the mode in certain circles to regard visitations of syphilis, and the only treatment thought worthy of attention was the invocation of saints. The point of view has since changed, and so, for the matter of that, has our system of therapeutics, although it is open to question whether the treatment proper of plague is attended by better results now than in the days which this little article brings before our eyes.

A Novel Point in Compulsory Notification.

A CURIOUS point was raised before the Southport Bench last week in some proceedings taken against one Alfred Plevin, of Birkenhead, for failing to notify a case of scarlet fever. It transpired that the defendant though holding "a number" of American diplomas was not a registered practitioner, and it was urged that the law did not apply to him. It was held, however, that as the law said "every medical practitioner" it was not restricted to duly qualified and registered practitioners, and he was accordingly fined £1 with costs. The validity of the conviction is questionable, for, since the defendant can lay no claim to the privileges of a registered practitioner he can hardly assume the responsibilities of one. On the other hand, he incurs certain responsibilities by posing as a medical practitioner; which some of the neighbouring practitioners ought to make it their duty to bring home to him as he seems to be doing quite a practice.

The Investigation of Cancer.

THE Royal Colleges of Physicians and Surgeons in London have adopted the recommendation of a special committee to the effect that the two Colleges shall consider and develop a scheme for investigating into the causes, prevention and treatment of cancer, for which purpose delegates shall be appointed by the Colleges to draw up a detailed scheme. The following gentlemen have been appointed delegates in accordance with the foregoing resolution:—As representing the Royal College of Physicians: The President, Sir William Church, Bart., Sir William Broadbent, Dr. Pye-Smith, Dr. Whipple, Dr. Payne, Dr. Rose Bradford, and Dr. J. F. W. Tatham. As representing the Royal College of Surgeons: Mr. H. G. Howse, President; Mr. J. Langton, Mr. H. Morris, Mr. H. T. Butlin, Mr. Watson Cheyne, C.B., and Mr. R. J. Godlee.

Whiskey and Small-pox.

DR. WOLSTENHOLME, of Abergele, has a special method of dealing with small-pox, which he described before a recent meeting of the Abergele Council. He first "puts a ring of vaccination round each infected house," and then feeds the people (? the patients) well and plies them freely with whiskey and water, whence his soubriquet of "the whiskey doctor." He claimed to have stamped out the disease in six weeks, which is more than the Metropolitan Asylums Board has been able to do in London.

The Fate of Dublin University.

A CORRESPONDENT writes:—"It is sad to learn that the fell disease of noble minds has attacked the ruling authorities of Dublin University. This renowned institution, which down from the days of great Elizabeth has been a kindly *mater doctorum*, is, though still a mere stripling of three hundred years, lapsing into a premature senility akin to dotage. Acted upon by the prevailing folly of the decadence of the nineteenth century, and perhaps harassed by nervous fears of threatened rivalry, the ancient University is contemplating the step of opening her doors to women. Weary of being the constant and faithful mother of learning in Ireland, she desires to conquer fresh fields, and to become the step-mother of blue-stockings. She fain would coquette with the Alexandra College, in order that in her fancied old age they might stroll along hand in hand down the paths of oblivion. Dublin University has many an enemy who will gladly welcome such a step on her part. Has she no friend who will check her? What will her sister Universities of Oxford and Cambridge say to her future feminine 'bachelors'? Will they recognise them, and, receiving them with open arms, confer *ad eundem* degrees upon them? We fear they will not, for they, though older corporations, have not yet lost their mental balance. Are women to be eligible for Fellowship? and may we expect to see a feminine provost filling the post once occupied by some of the most distinguished men of their day? Or are women to be allowed entrance on sufferance to scrape up the crumbs of learning which fall from their masters' table? The one arrangement is impossible, the other is undignified. Perhaps it is not yet too late, and Dublin University will still preserve her former calm and prescience in the midst of the clamour of female educationalists, and would-be constructors of new universities. Changes in Dublin University may be necessary if she is to maintain her old position, but not such changes as those which are at present talked of. To the authorities who would suggest such a 'reform' we fear the aphorism but too truly applies, *Quos Deus vult perdere.*" We deem it well to give publicity to these views, which, however old-fashioned they may seem to the rising generation, are held by unquestionably very respectable persons. There remains the question whether it is either dignified or useful to emulate the exploits of Mrs. Partington, of broom fame, in the apparently vain attempt to stem the tide of persuasive and invading womanhood. *Quod femina vult Deus vult.*

The General Medical Council.

A SPECIAL Session of the Council was opened yesterday (Tuesday) in order to discuss the questions at issue between the Council and the Royal Colleges of Physicians and Surgeons.

THE annual meeting of the National Orthopædic Hospital will take place on Friday next, 28th inst., at the Hospital at 4 p.m., his Grace the Duke of Marlborough in the chair.

Small-pox in London.

THE outbreak of small-pox in London continues to progress steadily. The number of cases under treatment in the Metropolitan Asylums Board's hospitals at midnight on Sunday, the 23rd instant, was 1316. On Tuesday, the 18th, there were 63 fresh cases; on the 19th, 54 fresh cases; on the 20th, 73 fresh cases; on the 21st, 54 fresh cases; on the 22nd, 44 fresh cases; on the 23rd, 25 fresh cases; and on the 24th, 47 fresh cases. The disease has invaded another Poor-law infirmary in the East End, namely, that of St. George's East, and several patients have been removed, including one seventy-four years of age. The chief incident of the week arising indirectly out of the London epidemic was the attempt in the House of Lords, by Lord Newton, to obtain the repeal of the exemption clause of the 1898 Vaccination Acts. The measure was thrown out on division, but the debate made it abundantly clear that the conscientious objector is not regarded favourably in the Upper House. Lord Newton's proposal was to bring that hybrid offspring of Mr. Balfour's Act to a premature decease in 1903, whereas it expires automatically twelve months later. In the Commons Mr. Corrie Grant, who is a well-known anti-vaccinationist, asked various questions as to the facilities Government would feel inclined to grant in order to secure the more efficient isolation of persons who had come in contact with small-pox cases. In the midst of the present disastrous outbreak few of the anti-vaccinationists have had the courage to air their fanciful theories as to the best means of preventing small-pox. It certainly argues a good deal of courage for any individual who aspires to be regarded as a serious politician to air his antivaccinationist views in Parliament at the present juncture. If Mr. Corrie Grant and his small band of fellow-faddists are right, then the medical profession are wrong. In this particular detail, however, it so happens that sanitary experts will cordially approve of any steps that are likely to secure the prompt isolation of "contacts." Up to Friday night last, the 21st, the gross number of admissions of small-pox cases to the metropolitan hospitals was 3,561, and the highest number in a single day 93.

A Hospital Dispute in Scotland.

A SOMEWHAT remarkable dispute has arisen between the honorary medical staff and the managers of a small hospital in Morayshire. The institution in question is the Forres Leanochoil Hospital, which has sixteen beds and receives paying patients. It appears that recently Dr. Bruce, a newcomer in the district, attended a patient at the hospital, under a rule which we quote on the authority of the *Aberdeen Journal* of February 15th, to the effect that the medical staff shall attend all patients "unless any of them express a desire to be under the care of their ordinary medical attendant or of the medical officer who sent them." Shortly afterwards Dr. Bruce received a round-robin from

the medical staff asking him to discontinue attendance or to remove his patients. Dr. Bruce declined to adopt either course, and a month later the managers requested him not to attend, pending a revision of the rules. He was duly elected an honorary medical officer to the charity, and the rest of the staff appear to have resigned in a body. In a dispute of this kind there are always wheels within wheels, and it is difficult to arrive at the exact truth of the matter. Whatever may have been the supposed justification of the medical staff for adopting so strong an attitude as that indicated in the report given by the *Aberdeen Journal*, it seems fairly evident that Dr. Bruce was within his rights if his reading of the rules be correct, namely, that the wards were open to every qualified man in the burgh of Forres. It is to be hoped that it is not yet too late to come to some amicable understanding in a dispute that must detract from the dignity of the medical profession.

Kitchen Hygiene v. Kitchen Physic.

DR. W. T. FERNIE has recently published an interesting little work bearing the somewhat ambiguous title of "Kitchen Physic." While much might be said in praise of the contents of this book, it is not easy to defend the rather striking appellation adopted by the author. The kitchen is hardly suited for a dispensary, and its presiding geniuses are not usually considered as trained in the science and art of medicine. Physic concocted under the direction of the cook and administered by the housemaid is certainly open to serious objections. But it is not our purpose to consider the merits or dangers of kitchen physic; we wish merely to point out that the ignorance, neglect, and sometimes superstition, only too prevalent in kitchen administration, leads not infrequently to a widespread need for effective and scientifically selected "physic." An Englishman rightly considers his house his castle, but most householders go through life in profound ignorance of the doings in the kitchen. Most men pride themselves on the sanitary arrangements of their home. They take a minute interest in all pertaining to drains, lavatories, and bath-room. Much study and considerable labour is expended in the selection of materials in the decoration of the house which shall be perfectly innocuous. Endless trouble and expense is undertaken to guard the home from infectious diseases and toxic ills. The inmates are often carefully educated in matters pertaining to the prevention of disease and the preservation of healthy life. The modern nursery is now simply "run" on hygienic principles. The doctrine of fresh air, pure water, and much light is being carried out with vigorous practice. But amidst all this reform a stubborn conservative spirit is still dominant in the kitchen. It is remarkable that hygienists and physicians but rarely venture to face the realms devoted to the culinary art. The practitioner often blames the drains, complains of the water, grumbles at the lack of air; but when does he ven-

ture to enquire into the ways and means of the cook? There would be no difficulty in showing that the selection, preservation, preparation and serving of the food of a household are among the most vital factors in influencing its health. Much of the problem of life can be expressed in terms of food, and much of the indisposition and many of the minor ailments of every-day life are directly the outcome of a neglect of hygienic practice in the kitchen. If the illnesses met with in "high life" are to be effectually dealt with, the ignorance and neglect often made manifest in "low life" must not be forgotten. We hope Dr. Fernie will see fit to supplement his discourse on "Kitchen Physic" by a work dealing with "Kitchen Hygiene," and we would suggest that it should be written for and dedicated to those who serve our comfort and sometimes ruin our health from the mysterious and religiously guarded "kitchen."

The Disruption of Victoria University.

THE threatened disruption of the great federal university of the North is a matter which deeply concerns all interested in the educational welfare of this country. To the medical profession the question is of great importance. At a time when co-operation and co-ordination in matters educational, and particularly in medical training are essential, the proposal to smash up an existing institution in the height of its vigorous life is little less than a national peril. We are glad to see that at a largely attended special meeting of Convocation of Victoria University, on Wednesday, a resolution was carried: "That Convocation disapproves of any policy involving the disruption of the Victoria University as being detrimental to the best interests of higher education." We understand that Earl Spencer, the Chancellor of the University, is arranging for a special committee to consider the whole question. Each College is to nominate four members; the Chancellor has selected as his nominees: Sir Richard Jebb, M.P., Sir Henry Roscoe, and Dr. Clifford Allbutt, and Convocation have chosen Professor Smithells, of the Yorkshire College, Leeds, to represent them."

"Faith-healing" in Germany.

IF there be any saving virtue in Royal autocracy, it may surely be witnessed in the present attitude of the German Emperor towards the irregular medical practices known as "faith-healing," "Christian Science," *et id genus omne*. It is reported from Berlin that astounding revelations have recently been made in the Press and in the Imperial Diet concerning the practices of certain persons who call themselves "prayer doctors." These reports have drawn the attention of the Emperor to the fact that belief in the efficacy of prayer unaided by medical science has many adherents in aristocratic Potsdam circles. With characteristic energy, his Majesty is adopting measures forthwith to sweep this Augean stable free of its mass of mystical and revolting quackery. The attitude of Germany with

regard to irregular medical practice has always been ahead of that adopted here at home in the United Kingdom, where the General Medical Council exhausts its energies in harassing and controlling qualified medical men, while it ignores the inroads of unqualified persons both upon the health of the public and the pockets of the profession. As regards practices of the faith-healing type, which have roused the just indignation of the German Emperor, it may be asserted that they flourish in the United Kingdom to a well-nigh incredible extent. Among the followers of these mystic faiths may be found a host of persons of rank and position in Society. A good strong medical Act would do much to advance the general health of the nation and to sweep away these parasites of society. What steps are the General Medical Council and the profession taking to secure a reform of the present defective Acts?

Robert Barry, M.D., R.U.I., D.Sc., F.R.C.S.I.

WE regret to announce the death of Dr. Robert Barry, of Limerick, which took place on the 8th inst. Some time since he fractured his leg, and since then has been in poor health, but it was only a few days before his death that his condition gave rise to any anxiety. Dr. Barry was Medical Officer of Health for Limerick, and Medical Officer of the Railway Labourers' Union. He was very popular, and his death is deeply regretted by all classes of citizens.

Osteopathy and British Readers.

OF all the foolish quackeries ever foisted upon credulous humanity one of the silliest and most grotesque is that which flourishes in the United States under the title of osteopathy. An attempt has been made in that country to induce the New York Legislature to recognise the followers of this cult and to place them on the same level as the allopaths and homœopaths. For the credit of our American cousins it is to be hoped that they will continue their refusal to have any commerce with that particular form of medical quackery. Like the Christian Science fraud, which seems to be a kind of first cousin, it is cruel and heartless, inasmuch as it professes to cure all kinds of dangerous maladies by methods that are on the face of them worthless. It is somewhat surprising under these circumstances to find a respectable provincial journal, to wit, the *Manchester Daily Despatch*, publishing a prominent illustrated article upon osteopathy. The subjects dealt with pictorially are enough in themselves to condemn the whole thing. A girl is being stretched on a table to cure consumption "by removing the compression of the lungs"; another is having her neck massaged to cure diphtheria. Writer's cramp, which is usually supposed to attack the hand, is being treated by manipulation of the neck; whilst insanity is tackled by "setting a bone in the neck." The fantastic basis for the the "discovery" is said to be the manual readjustment of parts of the body that have become mechanically deranged, and have thence given rise to various

kinds of illness. Should osteopathy be adopted by any weak-minded inhabitant of Manchester, we do not envy the Editor of the *Despatch* for the part he has played in introducing such dangerous matter to the notice of his fellow citizens.

How to Avoid Small-Pox.

AT the present moment, when the air is thick with small-pox and rumours of small-pox, the subject has an evergreen fascination for catchpenny journalism. Thus, in a London evening newspaper, last week, appeared an article under the heading, "How to avoid Small-pox." It is hardly needful to say that the advice given beneath that sensational title was absolutely worthless. The main direction was to wear smooth-faced outer clothing that would harbour as little dust as possible, and to supplement the outer husk with an inner one of flannel underclothing. This grotesque absurdity is crowned by the grave statement that "flannel clothing alone will preserve the wearer from infection when he would otherwise inevitably fall a victim." This rigmarole of nonsense—that is to say, viewing the situation from a medical point of view—suggests the question whether there is really any scientific way of avoiding small-pox. It need hardly be remarked that no imaginable sort or kind of clothing whatsoever would protect a person from infection were he brought into contact with the germs of the disease. He would "take" the malady with equal ease and certainty were he clothed in rough clothes or in smooth clothes, in silken attire or in rags, in flannel, broadcloth, fustian, muslin, satin, or what not. The best way would undoubtedly be to keep away from infection, but unfortunately that is just what we are not able to do, for the poison may lurk in cabs, or omnibuses, or theatres, or churches, or shops, or railway carriages, or be brought to our houses by the milkman, or the charwoman or even in the clean clothes basket. The only other thing worth mentioning is vaccination and revaccination, which reduce the chances of catching small-pox almost to vanishing point. That sums up the view of a medical journalist on the alluring topic "How to avoid small-pox."

Tuberculosis and the Postal Service.

IN view of the rumour that consumption was common among the staff of the Postal Service, Mr. Austen Chamberlain has explained that, comparing the mortality from phthisis and cognate diseases occurring among the employés of the Post Office with those in the country at large, the former returns are the more favourable. This is, perhaps, reassuring, but it is very desirable that the authorities should see that such steps as are advocated by the Association of British Postal Medical Officers for the prevention of tubercle among postal employés should be adopted. Considering the large number of young females living an indoor life in various Post Offices departments, it is most necessary that a thorough periodical examination should be made. This is not only desirable for the sake of the

employés, but necessary for the well-being of the community.

The Manchester Medical Guild and the Midwives' Bill.

THE Manchester Medical Guild have circularised members of Parliament in reference to the Midwives' Bill now before Parliament, pointing out that the Bill in question does not prevent practice by untrained women, and makes no provision for qualified medical assistance even in difficult cases, and moreover, makes no provision for nursing after labour. On the other hand, it contravenes the Medical Acts, threatens to cause considerable friction between the newly-instituted midwives and the medical profession, and creates the dangerous precedent of allowing a non-elective body, *e.g.* the proposed Central Midwives' Board, to make a requisition at will, and without limit on the local rates. The scheme of a Bill which would not be open to these objections accompanies the circular.

The Quarantining of the Inmates of Infected Houses.

THE Local Government Board has issued a circular deprecating the quarantining, unless under special circumstances, of the inmates of houses infected with small-pox, on the ground that such course is unnecessary in districts in which sanitary matters are properly administered and vaccination and re-vaccination are efficiently carried out. In the case of laundries and similar institutions, however, it is admitted that some such steps may be desirable. Nevertheless, local authorities may supply food, &c., to inmates of a temporary shelter provided while the dwellings are undergoing disinfection.

Patrick Manning Kelty, M.B., L.R.C.P.Ed., L.S.A.

WE regret to announce the death, which took place on the 21st inst., of Dr. Patrick Manning Kelty, a prominent practitioner in Blackpool, in his seventieth year. Dr. Kelty was the son of Fleet-Surgeon T. Kelty, R.N., and was educated at Dublin. For many years he carried on a large practice at Walsall until, his health breaking down, he moved to Blackpool some twenty years since, where he was very successful, and became very popular with all classes of his patients, thanks to his genial disposition and sterling character.

No Apology!

DR. THOMPSON, one of the public vaccinators for Northampton, was called upon a day or two since to answer a charge of having vaccinated certain children without their parents' consent. Although it appears that the children came to his surgery for the purpose, he was directed to make an apology in the public Press, a step which, it may be hoped, he will firmly refuse to take.

AMONG the influential names recently added to the long list of Vice-Presidents of the Vaccination League are those of the Bishop of London, Arch-

deacon Sinclair, and Lord Newton. It will be remembered that Lord Newton recently introduced a Bill into the House of Lords on the question of vaccination. Those who are desirous of obtaining free literature dealing with the advantages of vaccination, or of organising popular illustrated lectures on the subject in their respective districts, should apply to the offices of the Vaccination League, 110, Strand, W.C.

SIR JOHN TUKE has given notice of his intention to move the rejection of the Midwives' Bill at present before Parliament.

PERSONAL.

DR. ALFRED HILL has resigned the post of Public Analyst to the Birmingham Corporation, in consequence of the great increase of work in the Health Department.

MR. HARRY CROOKSHANK, F.R.C.S.Ed., has had conferred upon him the Grand Cordon (First Class) of the Imperial Order of the Medjidie, in recognition of the signal services which he has rendered in Egypt.

PROF. VIECHOW continues to make satisfactory progress towards recovery, and is now allowed to walk about his room. Hopes are entertained that he will ultimately regain the full use of the injured limb.

DR. HUDSON, of Scarborough, met with a nasty accident last week, as the result of which he fractured three ribs and sustained some severe bruises. We regret to hear that he is likely to be incapacitated for work for some time.

DR. BARR, of Leeds, and Dr. West Symes, of Halifax, met with an alarming accident last week when sleighing in the neighbourhood of the latter city. The horse bolted, and they were thrown out, fortunately sustaining comparatively slight injuries.

MR. FRANK POSTLETHWAITE, M.B.C.S., of Perranporth (Cornwall), has been awarded the silver medal of the Dutch Humane Society for boarding the wrecked vessel "Voorspoed" off Perran Beach in March, 1901, in order to render assistance to the survivor of the crew.

DR. W. H. DAVIES, of Abercarn, has had to apply to the Bench for protection against the wife of an electrical engineer, who for some reason has taken a dislike to him, which she manifested a day or two since by firing a revolver at him through the window, an offence for which she will shortly be tried.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE HEALTH DEPARTMENT.

A CONSIDERABLE time ago we referred to a certain element of unpleasantness existing in the Health Department of the Corporation of Glasgow between Dr. Chalmers, the Medical Officer of Health, and Mr. Fyfe, Chief Sanitary Inspector. Both gentlemen are recognised as able and competent servants of the Corporation, but considerable friction has unfortunately been maintained between them for a long time now. Dr. Chalmers, who should unhesitatingly have, and believes he has, the supreme charge, has frequently given instructions

to officials, which Mr. Fyfe has resented, he thinking that the medical officer of health has no right to interfere with his (Mr. Fyfe's) department. If his duties are clearly defined in that direction, it is a state of matters that does not generally obtain. At any rate, the acute stage has now arrived, and the Corporation has now discussed the unpleasant state of affairs which has continued for several years, and has sent back for the reconsideration of the Health Committee, a minute which it presented to the Town Council after long and laborious consideration, to the effect that an extra medical officer of health should be appointed, with supreme charge. This proposal has been much discussed and severely commented upon. To carry it out would certainly place the present medical officer of health in a very invidious position, and at the same time we do not see that it would be an arrangement that would lead to amity existing between the two gentlemen referred to. The matter is now in the hands of an enlarged committee of business gentlemen, who in the interests of a large city, at present suffering from an epidemic of small-pox, must not shrink from discharging as expeditiously as possible what may be an unpleasant duty in a business-like way. Whatever decision may be arrived at we would emphatically repeat that the medical officer of health should be invested with supreme power, and apparently that was recognised by the Health Committee when they proposed the appointment of an extra medical officer, who was to have complete control of the health department of the city.

GLASGOW SMALL-POX EPIDEMIC.

After a short respite Glasgow has again been visited with an outbreak of small-pox which is now assuming somewhat serious dimensions. There are at present in Belvidere Hospital 172 cases. Last year the epidemic was largely confined to the east-end, but on the present occasion the cases in hospital have been received from various districts of the city, and the recrudescence is still showing a tendency to diffuse itself over a much wider area. The Health Committee of the Corporation displayed admirable zeal last year, and were most energetic in their efforts to stamp out the disease by urging re-vaccination in a very thorough manner, and offering to the citizens, rich and poor alike, every facility for getting free vaccination promptly performed. Notwithstanding the hearty response on the part of a numerous section of the community to the appeal issued by the Corporation for speedy re-vaccination, there remained a large residuum who failed, or refused, to avail themselves of the offer made, even after a house-to-house visitation on the part of the medical men. This considerable residuum is a serious menace to the lieges at the present moment, and the problem requiring immediate attention is how to get these recalcitrants persuaded to submit to re-vaccination for their own sakes, as well as that of their neighbours. A solution of the matter might be found by an appeal to all employers of labour again, and for them to ascertain the number of unvaccinated in their employment. There are, of course, other means which might be adopted. With the clear and pronounced knowledge we now possess of the efficacy of vaccination in arresting the spread of small-pox, and having the disease stamped out, it becomes an economic question of the most urgent importance to have every individual vaccinated. In Scotland infants require to be vaccinated within six months of birth, but at a time like the present parents should have their children vaccinated within a month or two of birth. At a meeting of the Corporation a few days ago, Mr. John Carswell, who is a medical member of the Town Council, made the somewhat startling statement, to the surprise of many present, that the near proximity of the small-pox hospital was a source of danger to the lieges, and was probably responsible for the spread of the disease, at least in the east end of the city. Mr. Carswell, being a member of the Health Committee, was found fault with for not making his statement at a committee meeting, instead of reserving it for a meeting when reporters were present, and through the channel of the Press reaching the public ear. Coming from a member of the medical profession it was calculated to attract considerable atten-

tion, and on the whole has elicited rather unfavourable comment.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE ANDERSON FUND.

THE Committee forward the appeal for aid for the widow and two sons of the late Mr. B. B. Anderson, F.R.C.S., and beg to announce that the subscriptions now received amount in all to £202 5s. 6d., and to request intending subscribers to kindly forward their donations at once, marked "For the Anderson Fund," to the Manager, of the Union Bank of London, Chancery Lane, London, as it is definitely proposed to close the account on the 28th inst.

A strong hope was entertained of collecting at least £500, the sum, it might well be remembered, fixed by the jury by their verdict in Mr. Anderson's favour in "Anderson v. Gorrie and others."

It is still earnestly desired that the £202 now in hand may be largely augmented before the Fund closes on the last day of this month.

I am, Sir, yours truly,

WALTER MONNINGTON, Hon. Sec.

7, Fig Tree Court, Temple, E.C.,
February 18th, 1902.

The following is the further list of subscriptions to date, exclusive of those kindly collected and already announced by Dr. Alfred Cox, of Gateshead:—

	£	s.	d.
Surg.-Major H. de Tatham, Ret. I.M.S., London ...	...	3	3
Dr. W. B. Haggard, Davos Platz ...	...	2	0
Dr. T. M. Watt, Goxhill, Lincs... ..	...	1	1
Dr. A. Smythe, Harrogate	...	2	0
Lord Hawke, Yorks.	...	1	1
Dr. Brazil, Bolton	...	1	1
O. S. M.	...	0	10
Dr. W. D. Stone, Cricklewood	...	1	1
Dr. Walter Edmunds, London	...	1	1
Dr. E. B. Fennell, Kirkby	...	1	1
Dr. H. P. Snook, Weymouth	...	1	0
Dr. Petch, York	...	1	0
Dr. A. E. Porter, Leeds	...	1	1
Major G. Gallen, R.A.M.C., Malta	...	3	0
Dr. W. Douglas, London	...	1	1
Dr. E. W. Emtage, Holsworthy	...	0	5
Dr. C. J. Warry, Surbiton	...	1	1
Surg.-Major Poole, Norwood	...	0	10
Dr. Robert Barnes, Eastbourne... ..	...	10	0
"Kirkham"	...	0	4
"L.R.C.P.," Sheffield	...	0	2

Per Dr. E. H. Wolstenholme for Medical Guild, Manchester	...	12	4

(Details of this last amount will be announced in next list.)

Literature.

WHITLA'S DICTIONARY OF TREATMENT. (a)

THE appearance of the fourth edition of this excellent work is sufficient evidence of its value to the medical practitioner. The field of modern therapeutics is so wide and developments so rapid that it becomes necessary for all in busy practice to have at hand some such means of ready reference. In reviewing a book of this kind it would be clearly out of the question to attempt to deal with the subjects *seriatim*, especially as a general survey shows that the matter is upon the whole accurate, and up to date. Turning to the section upon gall-stones, one finds a thoroughly practical summary of the

(a) "A Dictionary of Treatment." By William Whitla, M.A., M.D., Professor of Materia Medica, Queen's College, Belfast, &c., &c. Fourth Edition. London: Henry Renshaw, 1902.

treatment of that painful condition contained in about five pages. The advantage of olive oil is fully discussed, and the question of operative interference summed up fairly in the following sentence: "The practice of opening the gall-bladder early is steadily on the increase, though there can be no doubt that many lives are lost by a blind persistence in medical treatment." The author then adds to the value of his description by giving a concise account of the various methods of operation. Under the heading of "ganglion" no mention is made of the extremely common occurrence of simple and compound ganglia in cases of rheumatoid arthritis—to use the old-fashioned name for that disorder. The attempt to deal with conditions that are mainly surgical, however, is not always satisfactory. Under "periostitis" a meagre and inadequate description is given of the surgical aspects of that condition and of osteitis, while no notice is taken of their important relation to various bacterial invasions of the body. Under "acute rheumatism," researches into the bacteriology of the disease are dismissed with a brief and obscure allusion. That position hardly coincides with the attitude taken by some of the leading modern authorities, who boldly place acute rheumatism among the specific febrile invasions. Under "chronic rheumatism" the writer gives several pages of methods and of drugs that may be used in that obstinate malady. Few physicians of experience, however, would undertake thereby to do more than afford their patients some temporary relief, nevertheless, the most modern and efficacious remedy, superheated air, is dismissed in a brief sentence as follows: "The method of surrounding the affected limb with a dry heat of 250° or 300°, produced either by the gas burner or by an electric heat generator, has often given excellent results." The dry hot air at the temperature named was introduced by Mr. Tallerman, who applied it by means of gas, oil, or electricity. It is hardly fair, then, that the author should refer elsewhere (p. 344) to that method in the following way:—"For the stiffness and pains of chronic gout troubles the new electro-thermic generator is of much use, and A. S. Myrtle has obtained excellent results from it by a forty-minute local application of heat from 300° to 360° F." The apparatus thus described may be "new" in the sense that any flagrant plagiarism offers freshness, but there the "newness" ends. The history and the clinical results of the Tallerman treatment were published in scientific form years before the appearance of the apparatus mentioned in this volume. Apart from these few criticisms we have nothing but praise for this most excellent dictionary of treatment. The modern aspects of diphtheria are admirably discussed, and the article upon that subject may be taken as a type of the general erudition and practical way of handling up-to-date scientific knowledge. Dr. Whittle's book is a familiar object upon many a consulting-room table, and the present edition cannot fail to insure an increasing popularity. The book forms one of the well-known series of manuals.

PHARMACOPŒIA OF THE HOSPITAL FOR DISEASES OF THE THROAT. (a)

To every well-appointed hospital a special pharmacopœia is almost a necessity. Particularly is this the case when the study and treatment of special forms of disease are undertaken. The pharmacopœia of the Golden Square Hospital has rightly made for itself a position and a name. The present, the sixth edition, is based upon the former editions which were compiled by the late Sir Morell Mackenzie. Fortunately it has been reduced in size, owing chiefly to the fact that recent advances in the surgery of affections of the nose and throat have rendered obsolete much of the therapeutics formerly in vogue.

The present edition is in every way praiseworthy. It is well arranged, conveniently presented, the formulæ

are judicious and have been selected with great care and wise discretion. All formulæ comprised in the British Pharmacopœia have been excluded. The introduction of several valuable new drugs have rendered it necessary to add many fresh formulæ. Many useful additions have been made to the list of nasal douches, local anæsthetic solutions, and mixtures and pills for internal use. Most wisely an advance has been made in introducing the metric system of weights and measures alongside the old and time-honoured method. Throughout the arrangement is alphabetical. On grounds of convenience, both for patient and dispenser, many of the formulæ have been arranged so that they may be readily prescribed in the form of compressed tablets. There is also a well-designed diet table. The whole work has been well thought out and excellently carried through. It not only affords a necessary guide for the working of the hospital under the auspices of which it is published, but it will serve as an admirable model for other institutions, and will furnish much that is valuable and suggestive to the specialist and necessary to the general practitioner. We heartily commend this valuable collection of formulæ.

CAPITAL PUNISHMENT.

WITH all due deference to the powers of writing possessed by Mr. Josiah Oldfield, we must admit that his plea for the abolition of capital punishment under the title "The Problem of Capital Punishment" fails to convince. The book is undoubtedly clever, but its value for practical purposes is impaired by the idealistic tone of most of the arguments. One cannot but feel that in his endeavour "to be true to the humane within," the author has somehow allowed his enthusiasm to run away with him. Every rational person will agree that mercy and tenderness are often very effective agents in the reformation of character, but were they permitted the undue activity suggested here, punishment could not fail to generate into the sorriest of shams, and although, under these conditions, the world might become a Paradise to the criminal, to the law-abiding citizen it would speedily prove something quite the reverse. To destroy a man's faculties in the way described on page 177, and thereby render him paralytic or imbecile or both, will strike some people as a somewhat horrible alternative to capital punishment; but the author appears to find its justification in the idea that a man should be kept alive at all costs until he is "saved," though he at the same time omits to suggest a method by which, the "lay arm" having succeeded in destroying the mind, the "spiritual arm" may hope to prosper in the business of saving the soul. The chapter devoted to Anarchism is free from the extreme of sentiment which tends to lessen the worth of certain earlier passages, and its well-reasoned arguments merit close attention. Taken altogether the book may be said to be well written and interesting, but regarded as an attempt to elucidate the difficult problem of capital punishment it cannot be pronounced a success.

BROUARDEL AND GILBERT'S TRAITE DE MEDECINE. (a)

THIS volume deals with diseases of the pleura and mediastinum, and of the cerebro-spinal axis, treated by well-known authorities, such as Landouzy, Labbé, Galliard, and others. The chapter on pleurisy is an interesting monograph on the subject, in which Dr. Landouzy treats very thoroughly the question of tuberculous and non-tuberculous pleurisy, pointing to the inevitable conclusion that a very large proportion of cases of pleurisy are of tuberculous origin. This relationship, now generally recognised, has only been established on an irrefragable basis during the last twenty years or so; indeed, it was not until the discovery by Koch of the specific bacillus of tuberculosis that the relationship admitted of conclusive demonstration. We know now that two-thirds of all cases of

(a) "The Pharmacopœia of the Hospital for Diseases of the Throat, Nose, and Ear (Golden Square)." Edited by H. Lambert Lock, M.D., and Charles A. Parker, F.R.C.S. Ed., Surgeons to the Hospital. Sixth edition. Pp. 75. London: J. & A. Churchill. 1901. Price 2s. 6d.

(a) "Traité de Médecine et de Thérapeutique, publié sous la direction de MM. P. Brouardel et A. Gilbert. Vol. 8. Paris: J. B. Baillière et fils. 1901.

pleurisy are tuberculous, a fact which possesses an inestimable importance in prognosis. Another fact very clearly brought forward is the variable origin of the non-tuberculous cases, our old friend, pleurisy *a frigore*, being left quite out in the cold. Pneumothorax is another morbid state our knowledge whereof has greatly advanced of late years. This is also in from 70 to 80 per cent. a collateral symptom of tuberculosis, though it is a comparatively rare symptom in regard to the total number of phthisical patients, occurring as it does only to the extent of about 1 per cent.

Glandular and other tumours of the mediastinum are dealt with in what is really an admirable monograph by Dr. Boinet. Improved methods of diagnosis permit of much greater accuracy than was previously the case, and practitioners in general are more alive to their existence. The subject is a wide one, and we commend the author's comprehensive review of the clinical and pathological data to our readers.

The series of monographs which deal with the pathology of the cerebro-spinal axis occupy two-thirds of the volume before us. They are contributed by Ballat, P. Marie, Achard, and Vilippl, and are fully up to the standard we are entitled to expect from authors of their eminence. The various clinical phenomena are handled in a way which renders their comprehension easy to others than specialists in this department. The work is thoroughly up to date, the most recently discovered aids to diagnosis being described and applied.

This magnificent system of medicine, published as it is at the extremely moderate price of 12 frs. (about 10s.) per volume, constitutes a library in itself, invaluable to those who are sufficiently conversant with the French language to have recourse to it.

British Medical Benevolent Fund.

THE annual general meeting of subscribers to the British Medical Benevolent Fund was held on February 18th, Sir William Broadbent, Bart., the president, being in the chair. The report of the Committee and the Treasurer's financial statement for the past year were presented and adopted. In the Grant Department subscriptions amounting to £1,110 9s. 2d., and donations amounting to £369 8s. 3d. had been received, and £1,614 1s. had been distributed to 161 applicants in sums varying from £5 to £20. In the Annuity Department the income from capital had been £2,419 8s. 5d., of which £2,288 6s. 8d. had been paid to pensioners of the age of sixty and upwards, the number being now 114. The working expenses of the fund had been, as for so many years past, less than 5 per cent., and the accounts had been subjected to the usual strict investigation by a chartered accountant. The report stated that it was impossible to give adequate help even to the most distressing cases on account of the restricted means at the disposal of the Committee, and expressed a hope that every subscriber would endeavour to interest others in the work of the charity. Hearty votes of thanks were passed to the President and other officers, who were unanimously re-elected, and the meeting concluded with a warm acknowledgment of the support always given to the charity by the medical Press.

Death under Chloroform.

A DEATH under chloroform was the subject of an inquest at Liverpool on the 14th inst., the victim being a woman, age 22, who had just undergone an operation for the removal of a goitre at the Royal Infirmary. Death took place suddenly before consciousness was restored. The usual verdict was returned.

Dublin Death-rate.

THE average annual death-rate in the Dublin registration area for the week ending Saturday, February 15th, 1902, represents a rate of mortality of 27.5 in every 1,000 of the population. Diseases of the respiratory system caused 48 deaths, tuberculous disease caused 34 deaths, diseases of the circulatory system caused 18 deaths; 40 infants died during the week, 22 of whom were under one year old. In 12 instances the deaths were uncertified, there having been no medical man in

attendance. Within the city the death-rate in Clarence Street district, Summer Hill district, Blackhall Place district, and Castle Street district was 31.9 per 1,000, 36.9 per 1,000, 32.9 per 1,000, and 48.8 per 1,000 respectively.

A Practitioner Sentenced.

MR. JAMES WILLIAMS AYRES, L.R.C.P.Ed., of Liverpool, was tried at the Liverpool Assizes last week on a charge of manslaughter, and was sentenced to four months' imprisonment. In pushing a man out of his house he caused him to fall, fracturing his skull. The jury strongly recommended him to mercy.

A Bogus Doctor Convicted.

A MAN who went under the name of James Joseph O'Donnell was found guilty at the Liverpool Assizes of various frauds. His career was one extraordinary series of fraud and imposture. Representing himself as a qualified medical man, he negotiated with Dr. Wilding, of Hindley, for the purchase of his practice, obtaining possession of his horse, carriage, &c. The prisoner's real name is Burroughs, and he began life as a chemist's assistant in Tottenham Court Road. It is significant reflection on the lack of care sometimes displayed in such matters that the prisoner on one occasion actually obtained the appointment of House Surgeon to the Hope Hospital, Salford. Sentence has been deferred, but as he also pleaded guilty to bigamy, Mr. O'Donnell, *alias* Barrows, is not likely to resume his career of crime for some time to come.

Indian Medical Service.

THE following is a list of the candidates for His Majesty's Indian Service who were successful at the Competitive Examination held in London on February 10th, 1902, and following days. Thirty candidates have been passed instead of seventeen as previously announced:—

J. Macpherson ...	3,210	H. Halliday ...	2,629
W. C. Ross ...	3,086	F. E. Wilson ...	2,610
J. C. C. Kunhardt...	3,051	B. B. Paymaster ...	2,577
G. D. Franklin ...	3,026	H. Croesle ...	3,560
J. H. Gill ...	3,011	L. Cook ...	2,546
R. A. Lloyd ...	2,878	J. Forrest ...	2,490
F. A. F. Barnardo...	2,870	L. B. Scott ...	2,483
C. A. Gourlay...	2,853	J. H. Ferris ...	2,456
E. A. Walker ...	2,750	W. S. Patton ...	2,445
F. W. Sime ...	2,746	N. W. Mackworth...	2,409
L. L. Hirsch ...	2,713	W. L. Trafford ...	2,393
H. Ross ...	2,684	L. Eundall ...	2,365
H. E. J. Batty ...	2,666	E. C. C. Maunsell...	2,342
G. J. Davys ...	2,656	G. C. J. Robertson	2,277
A. J. V. Betts ...	2,650	D. T. A. O'Keefe ...	2,062

Royal College of Surgeons in Ireland.—Fellowship Examination.

THE following candidates have passed the examination for the Fellowship:—Mr. F. J. C. Heffernan, Miss M. R. Kapadia, Mr. H. Pringle, and Mr. M. J. Russell. The following have passed the primary part of the examination:—Mr. F. J. S. Heaney, Miss C. McCrea, and Mr. R. S. Pryce.

Society of Apothecaries of London.

THE following candidates passed at the February examinations in:—

Surgery.—W. V. Braddon (Section I.), T. S. Davies, E. N. de V. Dawson (Section II.), J. C. S. Dunn, E. Gauld (Section II.), S. F. Hickman (Sections I. and II.), H. Jacques (Sections I. and II.), C. C. Morgan (Section II.), E. Osborne (Section I.), P. G. Sheppard (Sections I. and II.), J. H. Williams.

Medicine.—J. E. Bolton (Section II.), E. Gillett (Sections I. and II.), C. E. A. Huddart (Sections I. and II.), M. E. S. Scharlieb (Sections I. and II.), C. Watson (Sections I. and II.).

Forensic Medicine.—D. Fletcher, M. E. S. Scharlieb, C. Watson.

Midwifery.—W. C. P. Bremner, I. Griffith, M. E. S. Scharlieb, R. H. Terry.

The qualifying diploma of the Society in Medicine, Surgery, and Midwifery was granted to the following candidates:—J. E. Bolton, E. N. de V. Dawson, D. Fletcher, E. Gillett, C. E. A. Huddart, P. G. Sheppard, and C. Watson.

Notices to Correspondents, Short Letters, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

WINTERING ON THE RIVIERA.

J. E. B. (Liverpool).—We referred your inquiry to our special correspondent now on the Riviera. He replies that the present season along the Mediterranean has not brought so many English visitors as usual. Consequently your patient will find no difficulty as to hotel accommodation for himself and friends. Rheumatic subjects do well at Cannes and Grasse, as the air is drier and more bracing than it is farther along the coast. At the former the Continental Hotel is a well-appointed establishment much frequented by English visitors, and is conveniently near the sea, the railway, English church, &c. Grasse is a few miles in the rear of Cannes, 1,150 feet above sea level, its views of sea and landscape being unrivalled on the shores of the Mediterranean. Nature has showered her favours here with a lavish hand, and one seems to breathe the scent of flowers—violets, roses, the mimosa, &c.—at every turn in this sunny corner, whilst we in England are enduring the rigours of winter. Grasse is surrounded with high mountains on whose slopes palms, orange trees, olives and pines luxuriate, rendering it a paradise for convalescents. Unlike Cannes, which is full of hotels, Grasse has but one important establishment of the kind, viz., the Grand Hotel. Of this we can speak personally in the highest terms, its homelike comforts and its magnificent prospect being unapproachable elsewhere. Our correspondent refers to the other subject of your inquiry in another column.

LIVERPOOL.—In our next.

A NEW SHAVING PASTE.

MR. EDMUND WHITE, in the *St. Thomas's Hospital Gazette*, gives the formula for an antiseptic shaving paste which our readers, or some of them, may be glad to have. It is an emulsion of paraffin wax made by mixing twenty-five parts of wax with two parts of tragacanth previously made into an emulsion, and a small quantity of lard or stearin, ten parts of alcohol, and q. s. of lavender oil or other scent (rose geranium would be preferable). An ounce of this paste is sufficient for six shaves.

AMENDE HONORABLE.

We are requested to publish the following:—

9, Manchester Square, W.
To Herbert William Allingham, Esqre.

DEAR SIR—I am very sorry to learn that certain references to you by name in my work entitled "What's What" have caused you annoyance, and that you consider them "calculated to damage you with the public and the medical profession."

I sincerely regret their insertion and shall omit from any future edition any such references, and, indeed, all mention of your name whatsoever.

I wish also to state that the references referred to were absolutely unauthorised by you or anyone on your behalf, and that you were in no way whatever responsible for, or a party to, such reference.

I need hardly say that it was very far from my intention to cause you damage or vexation, and, as it appears that my words have unwittingly done so, I authorise you to make any use of this expression of regret which you may think fit.

Yours obediently,

HARRY QUILTER.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, FEB. 26th.

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (30, Hanover Square, W.).—5 p.m. Meeting.

HUNTERIAN SOCIETY.—8.30 p.m. Mr. Reginald Harrison: Some Points in Practical Surgery suggested by the Study of the Life and Work of John Hunter. (Hunterian Lecture.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. W. McAdam Eccles: The Imperfectly Descended Testis, its Anatomy, Physiology, and Pathology.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. J. Smith: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. L. Williams: Hygiene of Mouth.

THURSDAY, FEB. 27th.

SOCIETY OF ARTS.—4.30 p.m. Mr. N. B. Wagle: The Industrial Development of India.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr. Corfield: The Etymology of Typhoid Fever and its Prevention. (Milroy Lecture.)

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Davis: Medical Anatomy and Physical Diagnosis.

THE HOSPITAL FOR SICK CHILDREN (St. Ormond Street, W.C.).—4 p.m. Dr. Voelcker: Demonstration of Selected Cases.

CHARING CROSS HOSPITAL.—4 p.m. Mr. Wallis: Surgical Cases. (Post-Graduate Course.)

FRIDAY, FEB. 28th.

CLINICAL SOCIETY OF LONDON (30, Hanover Square, W.).—8 p.m. Exhibition of Clinical Cases followed by Discussion. Patients will be in attendance from 8 p.m. to 9 p.m.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. W. McAdam Eccles: The Imperfectly Descended Testis, its Anatomy, Physiology, and Pathology.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chancery Street, W.C.).—4 p.m. Mr. W. Dodd: Clinique. (Surgical.)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith Road, W.).—5 p.m. Dr. Abraham: Skin Cases.

THURSDAY, MARCH 6th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Paper:—Mr. F. L. Daniel: Some Rare Cases of Sarcoma of the Thyroid. Clinical Cases will be shown by Dr. Cantley and others.

ROYAL SOCIETY.—Ordinary General Meeting at 20, Hanover Square. The chair will be taken at 8.30 p.m.

DUBLIN.

FRIDAY, FEB. 28th.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Surgery, College of Surgeons, 8.30 p.m.

Appointments.

BERRY, H. POOLE, M.B. Lond., Medical Officer of Health to the Grantham Corporation.

COOPER, ARTHUR, M.R.C.S., L.B.C.P. Lond., Honorary Consulting Surgeon to the Westminster General Dispensary.

CROWE, DANIEL, M.B. B.Ch. Dubl., Certifying Surgeon under the Factory Acts for the Ulceby District of the County of Lincoln.

DRAFFIN, DAVID KENNEDY, L.R.C.S., L.R.C.P. Irel., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., Public Vaccinator for the Merthyr Vale District of the Merthyr Tydfil Union.

FRY, CRADOCK A. M.A., M.B., B.C. Cantab., Honorary Assistant Surgeon to the Essex and Colchester Hospital.

MACRAE, F. ALBERT, M.B., M.S. Aberd., Medical Officer of Health for Dingwall.

POWELL, W. WYNDHAM, F.R.C.S. Eng., Honorary Surgeon to the Westminster General Dispensary.

ROBERTS, D. J., M.B., Ch.B., Medical Superintendent to the Westmorland Sanatorium for Consumption.

THOMAS, WILLIAM JOHN, L.R.C.P. Lond., M.R.C.S., Public Vaccinator for the Barroed District of the Merthyr Tydfil Union.

TROOP, WINIFRED, L.S.A., House Surgeon to the Mater Infirmarium Hospital, Belfast.

TURNBULL, C. C. L., House Surgeon to the North Devon Infirmary.

Vacancies.

County Borough of Blackburn.—Medical Officer of Health. Salary £550 per annum. Applications to Robert E. Fox, Town Hall, Blackburn.

Durham County Asylum.—Junior Assistant Medical Officer. Salary £150, with board, apartments, laundry, and attendance. Applications Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.

Galway Hospital.—Resident Medical Officer and Compounder of Medicine. Salary £30 per annum. Applications to S. J. Leonard, Clerk to the Hospital. (See Advt.)

Manchester Royal Infirmary.—Honorary Assistant Physician. Applications to W. L. Saunders, General Superintendent and Secretary. (See Advt.)

Manchester School Board.—Medical Officer. Salary £250 per annum. Applications to the Charles Henry Wyatt, School Board Offices, Deansgate, Manchester.

Rural District of Doncaster.—Medical Officer of Health. Salary £300 per annum. Applications immediately endorsed "Medical Officer" to F. E. Nicholson, Solicitor, Clerk to the Council, Union Offices, High Street, Doncaster.

Tottenham Urban District Council.—Medical Officer of Health. Salary £500 per annum. Applications to E. Crowne, Clerk of the Council, Coombes Croft House, 712, High Road, Tottenham.

Births.

CREE.—On Feb. 22nd, at Park Villa, Cheltenham, the wife of Major Gerald Cree, R.A.M.C., of a son.

Deaths.

BRODIE.—On Feb. 21st, at 1, Buckland Hill, Maidstone, Kent, of pneumonia, Lt.-Colonel J. F. Brodie, R.A.M.C., aged 48.

GALTON.—On Feb. 21st, at Shelsley Grange, Worcester, Frances Anne Adèle, widow of Robert Cameron Galton, Esq., M.D., aged 67.

MOXON.—On Feb. 20th, suddenly, at his residence, Loraine Place, Holloway, N., John Moxon, M.R.C.S.E., aged 67, only son of the late John Moxon, surgeon, of Leeds.

PORTER.—On Feb. 18th, Julia, relict of the late Henry Porter, M.D., F.G.S., of Peterborough.

STRAHAN.—On Feb. 21st, suddenly, S. A. K. Strahan, M.D., of the Middle Temple, Barrister-at-law, aged 48.

WAGGETT.—On Feb. 20th, at Perivale, Bournemouth, Florence Blechynden, the beloved wife of John Waggett, M.D., aged 78 years.

WOODHOUSE.—On Feb. 5th, at sea, on board the s.s. 'Ulunda,' Joseph Parker Woodhouse, L.R.C.S., L.R.C.P., second son of the Rev. Joseph T. Woodhouse, of Caterham Valley, formerly of Southport, aged 31.

The Hunterian Lectures

ON THE

ANATOMY, PHYSIOLOGY AND PATHOLOGY OF THE IMPERFECTLY DESCENDED TESTIS. (a)

By W. McADAM ECCLES, M.S.LOND.,
F.R.C.S.,

Hunterian Professor of Surgery; Senior Assistant Surgeon, West London Hospital; Assistant Surgeon, City of London Truss Society; Examiner in Anatomy to the Society of Apothecaries, &c.

ABSTRACT OF LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—The imperfectly descending testis has during recent years claimed an increasing amount of attention, and while there has not been advanced much that is novel, yet the importance of the lesion from a surgical point of view has been more clearly demonstrated. It is my intention in these lectures to bring together the chief facts so far as they are known at the present time concerning the anatomy, physiology, and pathology of the testis which has not reached its normal position in the scrotum.

ANATOMY.

The human testis may be arrested at some spot in the normal route along which it migrates, namely, within the abdomen, in the inguinal canal, just below the superficial abdominal ring, and in the higher part of the scrotum. These constitute non-descent, partial descent, or retention; or the testis,

FIG. 1.

A right testis in Scarpa's triangle. The right half of the scrotum is developed, but not distended. From a photograph of a man, æt. 35, who said his right testis had always been in this position.

having proceeded as far as the exit of the inguinal canal, may pass into an unnatural position, such as the perineum, Scarpa's triangle, the root of the penis, or upon the superficial surface of the aponeurosis of the external oblique muscle of the abdomen. These constitute abnormal descent or ectopia.

It would occupy too great an amount of time to do more than indicate the several conditions which have been considered to be the causes of the arrest of the human testis in its passage along the normal route of its transition. 1. Conditions associated with the mesorchium. 2. Conditions associated with the testis and its component parts. 3. Conditions associated with the gubernaculum testis. 4. Conditions associated with the cremaster. 5. Conditions associated with the route along which the testis has to pass. 6. Other conditions, such as the wearing of a truss preventing the onward passage of the organ into the scrotum. In some cases the body of the testis may be retained in the canal, while the epididymis and vas pass into the scrotum.

There are probably only two causes of the abnormal descent of the human testis, or ectopia of the organ: one is that the testis is drawn into its usual position by the traction of certain sets of fibres of the gubernaculum testis; the other is that the testis is pushed into its abnormal site by an advancing hernia. The actual regions in which they have been observed are the perineum, Scarpa's triangle, about the root of the penis, and towards the anterior superior spine of the ilium in front of the aponeurosis of the external oblique muscle of the abdomen.

FIG. 2.

A right testis at the root of the penis. The right half of the scrotum is developed, but not distended. A case of Mr. Bilton Pollard's recorded in the *Medical Chronicle*, December, 1895, p. 193.

(a) Delivered before the Royal College of Surgeons of England on Feb. 24th, 1902.

It is extremely doubtful whether the testis has ever reached the upper part of the thigh by a spontaneous passage through the femoral ring. The classical instances which are quoted in support of this view are not altogether convincing as to the exact path along which the testis moved, some of the cases being very inadequately reported. Nearly always with the testis in Scarpa's triangle the spermatic cord can by careful manipulation be traced, not through the femoral ring, but up to and through the superficial abdominal ring, thus proving that the organ left the abdomen by the inguinal canal, and it was only after its exit from the superficial abdominal ring that it passed into the upper part of the thigh. That a hernia in its advance may force a testis from its normal course into a position which is altogether unusual for it is fairly certain, and most, if not all, of those instances in which a testis is found lying on the aponeurosis of the external oblique muscle superficial to the inguinal canal are in reality examples of this pushing and not of the drawing action exerted by the fibres of the gubernaculum.

While thus reviewing the imperfect and the abnormal descent of the human testis it is well to remember in connection with the pathological conditions that may be associated with the same that what may be imperfect or abnormal descent in the human subject may be the natural or perfect condition in other animals.

The lecturer then reviewed the position of the testis as found in the various classes of the vertebrata.

There is some subtle influence at work in the testis of the higher vertebrates which renders full descent in the vast majority of cases necessary to, or concomitant with, full development. It is also a fact that the various pathological conditions associated with imperfect descent in the human subject are unknown, or almost unknown, in those animals in which the testes never transgress the limits of the abdominal wall.

The effect of imperfect descent upon the testicle itself, in so far as its anatomical characters are concerned, lies chiefly in the fact that, as a rule, the organ is smaller than its normally-placed fellow, or, at any rate, smaller than a testis should be of an individual of the same age whose testes are in their proper position. While, however, it is a truth that the testis is so frequently not of its usual magnitude when it is imperfectly descended, yet it must be remembered that this want of growth is not invariable, and that about 5 per cent. are of normal size in spite of their occupying situations other than the lowest limit of the scrotum. This proportion is undoubtedly a comparatively small one, and even in these, without confirmatory microscopical examination of the glandular structure, it is impossible to be quite certain that the testis, although apparently of its proper size, has not its ultimate tissue imperfect in its development.

There are at least three ways in which the abnormal condition of the imperfectly descended testis can be viewed. The first is that there has been an initial want of proper formation of the organ altogether apart from the want of complete descent. The second is that the organ proceeds in its usual growth up to the period of the commencement of sexual life, but never enlarges and undergoes that full development which should accompany the onset of puberty. The third is that the testis does acquire its normal size, and with it its complete physiological function at puberty, but that owing to its abnormal position it is soon involved in retrogressive changes, producing in the end entire atrophy of the seminal tubules and a consequent loss of activity. It must be confessed that there is still a want of clear evi-

dence in favour of any one of these three suggestions, and it may be possible that each should have its quota of cases placed under its respective heading.

Of recent years a considerable amount of attention has been paid to the want of development of the imperfectly descended testis, chiefly from the fact that there has been much difference of opinion as to what is the correct method of dealing with the organ when it is met with in the course of a radical operation upon an associated hernia. From a review of a large number of records, both published and unpublished, as well as from the examination of a considerable series of sections of imperfectly descended testes, as to the exact condition of the seminal tubules, of the presence or not of spermatozoa or of their partial formation, it would seem that it may be accepted as a working hypothesis that the testis so arrested is one that has very definite divergences from the structure of a normally placed and fully-developed organ.

FIG. 3.

Section of a testis removed from the inguinal canal of an adult, showing tubules fairly well-developed, but inactive, and numerous interstitial cells. ($\times 150$.)

When the structure of the tubules of a testis that has not reached its proper level is examined there will be found a very different histological picture in the majority of the instances. The tubules are fewer in number, smaller, and more widely separated from one another by interstitial tissue, consisting of loose connective tissue which is rich in blood-vessels in spite of the otherwise ill-development of the gland. Scattered throughout this will be seen nuclei belonging almost certainly to interstitial stroma cells. In some sections these appear to have undergone considerable increase both in number and size. Such interstitial cells are present in the connective tissues of the normal adult organ, but in comparatively few numbers. What their significance and function may be is still problematical. Possibly they are associated with an internal secretion of the gland, a secretion that may be needful for the full bodily development or sexual perfection of the man. The fact that they are found in apparently larger number in particular instances of imperfectly descended testes is a matter of great interest both from a physiological and a pathological point of view. The connective tissue, moreover, here and there contains some large lymph spaces. The basement membrane of the tubules derived from the connective tissue as well as the membrana propria are well-developed. The lumen of the tubules is

most commonly found occupied by a mass of granular debris containing a large number of nuclei of various shapes and sizes, these being probably separated from the cells lining the tubule. As a rule, neither spermatoblasts nor spermatozoa can be demonstrated in the tubules of imperfectly descended testes. In some instances, however, it is possible to show that there has been actual spermatogenesis, and this most usually in those testes which have passed into the perineum.

HUMANISED LYMPH.

By GEORGE FOY, M.D., F.R.C.S.,

Surgeon to the Drumcondra Hospital, Dublin.

ONE of the most marked objections to vaccination in this country in the past was the dread lest some impurity in the blood of those yielding the humanised lymph might be conveyed to those to be vaccinated.

The Government wisely decided on using pure calf lymph only, and the public showed their appreciation of the change by a much more ready acquiescence to the vaccination law. Of course there are those who oppose vaccination, conscientious objectors, and unconscionable objectors who gain a little cheap notoriety by their resistance to the law and have the momentary gratification of reading their observations on vaccination and preventive medicine in the evening paper.

Readers of a medical paper do not need any argument to tell of the blessing of vaccination and of the wonderful preventive power of calf lymph. But my readers may not be aware that humanised lymph may be used for an almost indefinite time without in any way losing its valuable properties or becoming the vehicle for the conveyance of disease. In the Republic of Mexico for close on a hundred years humanised lymph has been used; and in the opinion of Dr. Eduardo Liceaga, President of the Supreme Board of Health of the Republic, the humanised lymph is the more trustworthy. At least they consider that a person properly vaccinated with it needs not to be revaccinated, which is more than is, or can be, claimed for the preventive power of calf lymph.

To ensure good results and obviate all risk of infection by disease, the securing and selecting of the lymph is entrusted to four physicians in the city of Mexico, who keep four healthy children vaccinated; from these they take the lymph, and with all aseptic precaution preserve and distribute it throughout the country. To-day in Mexico they follow the system introduced by the Spaniards when they carried humanised lymph to their American colonies.

How this was done may interest those who take an interest in medical history, for such I translate it, from the writings of Don A. Gomez Ranera, and from a copy of the Royal decree and the "Estudios Historico" of the late Don Emilio Castelar. I give it with all the more pleasure for the expedition that carried the lymph to America was the one praiseworthy act of Carlos IV., The Unfortunate, King of Spain and of the Indies. In 1802 Europe had a short breathing-time from the succession of wars commenced by the French Republic and continued by Napoleon. The treaty of Amiens, signed March 27th, 1802, terminated the war between Spain and her ally, France, and Great Britain, and soon afterwards Dr. Francis Xavier Balmis, a name ever to hold in honour, induced Don Carlos IV. to fit out an expedition for the beneficent purpose of carrying lymph to the Spanish Indies. This humanitarian project was difficult of accomplishment at the time. Spain was impoverished and humiliated by the war just finished. Godoy, the Prince of Peace, Judas-like, had sold his country, and had a foretaste of the

sweets of his treachery. Don Carlos IV. was sold into exile, Don Fernando, his son, afterwards Fernando VII., was disinherited, and Spain and Portugal were already marked out into separate kingdoms for Godoy and the other instruments of Napoleon. Yet before the crash came the expedition was ready, and on November 30th, 1803, Dr. Balmis sailed from Coruña with the sole object of conveying to the Spanish possessions in both the Eastern and Western Hemispheres the priceless gift of vaccine lymph. He had the assistance of a number of medical assistants, and his second in command was Don Francis Salvani. He carried four healthy children, in whom the vaccine papule was ripening, and twenty-two healthy unvaccinated children, of whom he vaccinated four at once, at intervals of a week for each set.

The expedition first made the Canary Islands, then Porto Rico, hence they sailed to Caracas. On leaving Venezuela the expedition, having previously taken some children on board, divided into two, one division under Dr. Francis Salvani going south, and the other under Dr. Balmis going north, this latter called at Cuba and from thence passed west to Yucatan. At Yucatan the lymph being abundant, the northern division was further sub-divided, one portion under the charge of Dr. Francis Pastor undertaking the supplying of Central America, and the other under Dr. Balmis's care sailed for the port of Vera Cruz, and making his way inland, Dr. Balmis carried his humanised lymph into the Royal City of Montezuma, where for more than ninety years his scheme of its production, preservation and distribution has been followed.

On Sunday, September 7th, 1806, Dr. Balmis returned to Spain, where he had the honour of kissing his Majesty's hand. Since his departure he had crossed the continent of America, carried the precious knowledge of preventive medicine to the islands of the Pacific, to the Portuguese colonies, the Chinese Empire, and some of the British possessions. At Canton he left the balance of his stock of lymph with the physician of the English factory, and left for Macao, where he took ship in a Portuguese vessel for Lisbon.

In the following year Dr. Francis Salvani returned to his unhappy country to find his King a prisoner, his country a province of France, and the "puppet," King Jerome, masquerading in the palace of the Bourbons.

NOTES ON A HUGE ABDOMINAL CYST. (a)

By W. J. THOMPSON, M.D., L.R.C.S.I., M.R.C.P.I.

Surgeon to Jervis Street Hospital.

E. B., mechanical engineer, for some time working at Woolwich Arsenal, æt. 36, unmarried, was admitted to Jervis-street Hospital on October 9th, 1901, with the following history:—In April, 1899, while at particularly heavy work, he felt that he strained himself about the region of the stomach, and from that time he always felt uncomfortable about the upper part of the abdomen. In the following July he got an acute attack of English cholera and was obliged to remain from work for some days. From that period he was frequently subject to attacks of pain in the upper part of the abdomen accompanied with vomiting, but no diarrhoea. These became so frequent and severe that he had in the spring of 1900 to give up work. About this time he attended as an out-patient one of the London hospitals for what he himself described as dyspepsia. In May, 1900, he first noticed a swelling in the region of the liver and this gradually increased until it attained

(a) Read before the Section of Pathology, Royal Academy of Medicine, Ireland, Feb. 21st, 1902.

its present size. From the commencement of the swelling he had no pains—only a tight feeling—but the vomiting continued. He had a good family history; had himself always been strong and healthy, was 5 ft. 8 in. high, and before his illness weighed about 12 stone. He was temperate and regular in his habits and denied ever having syphilis or gonorrhoea. On admission he was found to be thin and emaciated, weighing 10 stone. The upper part of the abdomen was greatly distended in the right hypochondria, the epigastria and part of the left hypochondria, the right lumbar and umbilical regions—the point of most prominence being at the junction of the 8th costal cartilage on the right side; the costal cartilage was everted at this point. There was well marked bulging in the right flank and back, even when the patient was placed in the prone position. The swelling was absolutely dull on percussion, and fluctuation was with difficulty obtained. The face borders could easily be defined in the left hypochondria, left lumbar and inguinal regions. The following measurements were recorded:—Circumference at level of junction of 8th costal cartilage, 39 inches; at umbilicus, 38 inches; distance of top of ensiform cartilage from umbilicus, 8 inches; distance of umbilicus from pubes, 6½ inches. The urine was found to be normal in quality and quantity. No change could be detected under the microscope in the blood; he was not jaundiced; had not fatty stools; temperature was normal; heart and lungs sound; respirations quickened and shallow due to the pressure. The vomited matter was ordinary gastric, sometimes mixed with that of biliary origin; but at no time did he vomit more than what he consumed. For the first two weeks after admission he seemed to improve and put on 5 lbs. in weight; was able to take and retain more nourishment and be up and about. After that time he gradually got worse, the vomiting became more persistent, so much so that he had to be fed by nutrient enemata. He lost flesh rapidly, and shortly before his death, which took place on December 13th, he only weighed 8 stone 4 lbs. During the latter part of his illness the cyst became movable, and could easily be displaced from one side to the other. He was frequently urged to allow an operation, but would never consent. It seems from cases recorded that operations are frequently successful. Osler in his recent work on abdominal tumours, describes a case with history and symptoms almost similar to this one. His case was operated on and made a good recovery. The contents of the cysts evacuated was found to be dark, coffee-coloured fluid, containing granular *débris* and much altered blood with some fresh red blood corpuscles. The diagnosis arrived at was that it was a huge cyst, and that it was either in connection with the pancreas or omentum, or that it was situated in the lesser sac of the peritoneum; the first, that of the pancreas, being the most likely. The origin of such cysts is rather obscure; as usual, different authors put forward different theories. It is now generally held that they are of traumatic origin, and that they first commence as blood cysts. As far back as 1892 Mr. Jordan Lloyd, in a paper published in the *British Medical Journal*, then suggested that such cases were the result of contusions or traumatism in the upper part of the abdomen, and that this might be either attached to the pancreas or to the omentum, or to the lesser sac of the peritoneum. With this view Osler and other prominent writers agree. At the *post-mortem* examination, on opening the abdomen, there were a great number of adhesions but no ascitic fluid. The cyst was very movable, and, as you see, had the stomach stretched out and adherent to the anterior surface. The pancreas and descending aorta are embedded in its walls. Its circumference measured 32 ins. All the other abdominal organs seemed healthy, and there were no enlarged glands.

SMALL-POX has broken out at Sandhurst, and special precautions have been ordered with the object of preventing the infection gaining the Royal Military College.

A CASE OF SYRINGOMYELIA, (a)

By JAMES TAYLOR, M.D., F.R.C.P.,

Physician to the National Hospital for the Paralysed and Epileptic, &c.

THIS young woman, æt. 23, is the subject of syringomyelia. I saw her at the hospital a month ago. Five years ago, after bathing, she had what was called a poisoned hand. Apparently there was a gathering at the base of the index finger of the left hand, and that was opened. What attracted attention at that time was, that although a considerable incision was made into it she did not seem to mind the operation, and was complimented by the surgeon on her pluck and composure. The wound did not readily heal. As a fact there was no pluck, because she did not feel it. Afterwards the hand was contracted, and in the few years which elapsed there had been a gradual development of symptoms in the shape of weakness of the left arm, with claw hand and the vaso-motor disturbance of which evidence could be seen. Frequently bullous sores appeared on the fingers and hand, not, so far as the patient knew, caused by any external application, but probably from hot and irritating things which she could not feel, such as burning. There was wasting of the hand and shoulder, but she said she could walk fairly well. The knee-jerks were both exaggerated, ankle clonus could be elicited on both sides, as well as the extensor plantar response in the left foot. She had very marked anaesthesia to all forms of stimulation over the hand and lower part of the forearm. Higher up in the arm she had a certain degree of thermal anaesthesia and analgesia. Over the trunk there was a similar condition. On the left side of the face she had distinct thermal anaesthesia, and marked analgesia on the left side of the forehead. There was marked nystagmus, which was not uncommon in such cases, and lateral curvature of the spine. Apparently, until five years ago she was quite well, and he thought the condition probably depended upon some inherited peculiarity of the spinal cord, which, after the age of puberty, took on some modification which had resulted in a spread or greater dilatation of the canal, consequent encroachment upon the anterior horn of the left side in the cervical region, and the pressure probably also resulting in some degree of sclerosis in both lateral columns.

There is no doubt that in the five years the condition has progressed, but as the patient had been under my care only a month, I do not know the rate of progression. It seemed to be extremely slow, as was usually the case. As to dilatation, it is difficult to be sure, and one can only theorise. I have seen a large dilatation in the cord in which the canal undoubtedly played a part, because the epithelial lining of the canal was quite recognisable. Probably there is some congenital defect in the cord, the defect being associated with dilatation, which spreads so as to affect the cells in the anterior horns, probably by pressure, or possibly by the formation of gliomatous tissue in the neighbourhood of the canal, and that by means of that process the cells are encroached upon and their function interfered with, leading to the wasting which is present in this case. It also probably leads to encroachment on the strands which conducted the sensory impulses. A similar process probably also leads to sclerosis in the pyramidal tracts, giving rise to symptoms which the present patient has, namely, lateral sclerosis. In the first cord of that kind he examined there was evidence of those conditions.

In some cases one has to deal with a process of new growth, and in another cord which I examined, in which the symptoms were quite distinct but much more extensive and rapid, was one in which there was a gliomatous growth from the top of the cord to its termination. So in cases of syringomyelia there are two conditions; first, a cord with a congenital abnormality which took on some slowly progressive change, probably under some condition of stress, and another kind in which it is conceivable that the whole process was one of new growth starting in the way in which new growths did, of which

(a) Read at meeting of Harveian Society, Feb. 20th, 1902.

very little was known. Charcot's disease in such cases is rare. I have seen only one case, namely, in the elbow, which Dr. Galloway published in the *Lancet* ten years ago.

With regard to flushing, no doubt girls subject to the condition have the pretty pink and white complexion shown by the present patient, and I am inclined to associate that with some vasomotor disturbances analogous to what is present in the hands of this patient. This is all the more likely in a case in which there is definite evidence of involvement of the nerve.

A CASE OF CONGENITAL HYDRONEPHROSIS. (a)

By DANIEL F. RAMBAUT, M.D., B.Ch., L.M.,
Rotunda Hospital, Dublin.

The male patient from whom I removed post-mortem the hydronephrotic kidney which I have exhibited to-night, died on Jan. 8th, 1902. The cause of death was pulmonary phthisis. He had shown no symptoms or signs of kidney disease, and his urine was free from albumin. The right kidney, which showed the hydronephrotic change, appeared a little larger than the left, and weighed five and a-half ounces, or half an ounce more than the left. Its capsule was non-adherent, and its cortex appeared normal. Much absorption of the pyramids have taken place. The ureter was not dilated. The left kidney, the bladder, the prostate and the urethra appeared normal. Beneath the commencement of the right ureter there was a pouch of the pelvis, of the size shown in a rough pencil drawing. The urine in this pouch probably exerted at first a pressure in the commencement of the ureter which caused an obstruction to the flow of urine into the ureter. As the tension in the pelvis increased, this obstruction was removed and a flow of urine took place. In this manner it is possible to understand how an intermittent flow may have occurred. Perhaps this condition should be more accurately defined as one of congenital hydronephrosis, which is due to malformation of the upper end of the ureter or the junction of pelvis and ureter. Very rarely at the point of union of the ureter with the pelvis a kinking of the ureter occurs which causes an incomplete or intermittent obstruction. Intermittent obstruction is necessary for the development of hydronephrosis, for should the obstruction be complete the tension within the calyces will prevent the secretion of urine. Orth, in his "Pathological Anatomy," treating of hydronephrosis, says: "There is a congenital valvular formation in the ureters themselves, and likewise an abnormal valvular oblique insertion of the ureters into the pelvis, which may become closed with a pouch of mucous membrane. In such cases generally the ureter is not inserted in the usual position in the pelvis, but higher up, so that an emptying of the pelvis in the erect posture can only be established when the pelvis is filled above the orifice of the ureter." (Orth, "Lehrbuch der Speciellen Pathologischen Anatomie," II. Band). I should mention that there was no abnormality in the position of the renal artery, and the kidney was in no way a movable kidney.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

MEETING HELD FRIDAY, FEB. 28TH, 1902.

MR. HOWARD MARSH, F.R.C.S., President, in the Chair.

CLINICAL EVENING.

THE PRESIDENT showed a man who had sustained a dislocation of the semilunar bone, the displaced bone having been removed by operation; a skiagram thereof was shown by Mr. Mackenzie Davidson.

CASES ILLUSTRATING THE TREATMENT OF BRONCHIAL DILATATION AND BRONCHIAL CATARRH BY POSTURE AND RESPIRATORY EXERCISES.

Dr. EWART described the method which consists of keeping the foot of the bed raised, sometimes to a considerable height, whilst the shoulders are kept low, only the head resting on the pillow. The first case in which it occurred to him to carry out this indication has been published; others, including some cases of phthisis, have been under treatment. The method, however, had been previously thought of and described by Quinke. Posture such as that described, particularly if kept up continuously, fulfils the first essential by saving the tubes from accumulation and from irritation, and may thus in advanced cases afford protection against serious complications whilst freeing the patient from the evils of cough strain. Any other treatment is in this way given a considerable advantage. The respiratory exercises, the other part of the treatment which he recommended, are intended to improve the ventilation and the circulation in the damaged lung, and to reclaim for pulmonary tissue the bronchial spaces vacated by the previously retained secretions. Two patients were shown to illustrate the effects of the treatment.

LOCOMOTOR ATAXIA (?)

Dr. JOHN R. LUNN showed a man, *æt.* 65, whose present condition was as follows:—No paralysis of muscles, walks fairly well, no ataxia, can stand with his eyes shut and feet together. No tremors of extremities. Patellar reflexes absent on both sides. Plantar reflexes increased. Left pupil small, reacts to light; the right pupil dilated, and does not react to light. Sometimes there is incontinence of faeces and urine. The left shoulder-joint flail-like, very movable, and when moved does not complain of pain. The muscles of the upper arm (left) are not markedly wasted. Slight grating in the joint. The last phalanx of the right thumb atrophied, and can be hyper-extended on the proximal phalanx, and most of the joints are deformed in the right hand in some way, which the patient attributes to an accident. The patient seems to have improved somewhat under antisiphilitic treatment.

POLYARTHRITIS IN A MAN, *ÆT.* 30.

Dr. LUNN also showed a man, *æt.* 30, who three years ago noticed pain on the left ankle, which began to swell, and remained swollen for twelve months, and then the right began in exactly the same manner. About eleven months later both wrist-joints began to swell, and then the right knee. At present there is a good deal of thickening round both ankle-joints, and fluctuation can be obtained; they are tender, but not red or hot. There is also well-marked flat-foot (bilateral) and swelling in the right knee-joint; muscles of the calf are much wasted. Both wrist-joints are swollen and painful; also the metacarpo-phalangeal joints of the first, second, and third digits on the right side, and first and second on the left hand. Thenar eminence on the right side is wasted, but not on the left. No headache or vertigo. The pupils act to light and accommodation. The knee-jerks are brisk on the left side, not obtainable on the right, apparently owing to the swelling of the knee-joint. Never had any rise of temperature. The patient had not improved under any treatment.

OSTEITIS DEFORMANS, WITH SKIAGRAPH.

Dr. LUNN also showed a man, *æt.* 72, who presented the characteristic lesions of osteitis deformans, together with skiagram of same.

EXCISION OF THE LOWER END OF THE ULNA FOR AN OLD COLLES' FRACTURE.

Mr. CUTHBERT T. WALLACE showed a man, *æt.* 55, who was admitted in August, 1899, for loss of power in the hand in consequence of a Colles' fracture, which he had received some time previously. The grasp of the hand was very weak, and incapacitated him from doing any useful work. There was much abduction of the hand, and flexion was extremely limited, owing to the lower end of the ulna overlapping the carpus. About three quarters of an inch of the ulna was removed through an incision on the inner side of the wrist.

(e) Read before the Section of Pathology, Royal Academy of Medicine in Ireland, Feb. 21st, 1902.

Skigrams showed the condition before and after operation. Power has returned, so that the patient can follow his occupation.

SARCOMA OF THE SYNOVIAL MEMBRANE OF THE ANKLE-JOINT.

Mr. G. H. TURNER showed a man, *æt.* 28, who three weeks after a blow, noticed swelling in front of right ankle, which had increased slightly in size since. He cut down upon the tumour, which was found to be a solid growth springing from the synovial membrane of the joint, the latter being opened as the tumour was removed. Dr. Rolleston reported the growth to be "a mixed-celled sarcoma containing a few giant-cells."

UNION BY SECONDARY SUTURE OF AN ILIO-LUMBAR INCISION AFTER THE SIMULTANEOUS EVACUATION OF AN ABSCESS AND THE EXCISION OF THE DISEASED APPENDIX, THE ABSCESS HAVING RECURRED FOR THE FOURTH TIME.

Mr. W. G. SPENCER showed a man, *æt.* 38, who was operated on January 9th for an abscess extending from the liver downwards, behind and external to the ascending colon and cæcum, into the pelvis, containing foul pus and gas. Within three years an abscess had formed three times before, and had been incised or had been allowed to burst through the scar. The incision gave room for the evacuation of the abscess, the breaking down of its loculi, and then the removal of the diseased appendix, which was buried in inflammatory tissues behind the cæcum and ascending colon. The cavity was then filled with iodoform gauze. A week later healthy granulations lined the cavity, and the temperature had become normal. The whole wound was therefore sutured, and sound union has followed.

PARALYSIS OF THE CERVICAL SYMPATHETIC.

Dr. PUEVES STEWART showed a man (soldier) who was wounded fourteen months ago by a Mauser bullet, which entered the left side of the neck one and a-half inches below the mastoid process, and came out in the seventh right intercostal space in the posterior axillary line, lodging in his bandolier. The bullet thus passed in front of the vertebral column. He had temporary total paralysis of the right arm, which gradually cleared up. There was some hæmoptysis and slight dysphagia for a few days only. Ever since the injury the sight in the right eye has been less acute than in the left, and he has noticed that he does not sweat on the right side of the face, scalp, neck, or upper limb. The lesion is apparently one of the first dorsal nerve-root on the right side.

SPLENIC ANEMIA WITH A SPLENIC BRUIT.

Drs. ROLLESTON and LAWRENCE JONES showed a man, *æt.* 22, a carpenter, who had noticed a swelling in his abdomen for four years, increasing in size. No history of malaria or syphilis. Two years ago he had an attack of epistaxis, and since then he has had repeated attacks of epistaxis, hæmatemesis, and mælena. He has considerable enlargement of his spleen. The blood shows anæmia of what is usually called the chlorotic type. Red blood corpuscles 2,400,000, Hg. = 25, and some diminution of the leucocytes; the highest number counted after a febrile attack (? influenza) being 4,600 per c.c., the lowest 3,530. There is apparently no change in the relative numbers of the varieties of leucocytes. There is a distinct blowing continuous murmur to be heard over the spleen, most distinct at the back in the ninth space, just outside the scapular line, and in front, in the ninth space, just posterior to the anterior axillary line.

Mr. W. G. SPENCER suggested removal of the spleen.

IDIOPATHIC MUSCULAR ATROPHY ASSOCIATED WITH PECULIAR PIGMENTATION OF THE LEGS.

Drs. S. VERR Pearson and ROLLESTON showed a man, *æt.* 22, who eight years ago had scarlet fever, in the second week of which there were rheumatic pains and swellings in the knees. Weakness in the back noticed a week later, followed by wasting of the thighs. Steady progress of the disease since onset. No similar affection in his relations. Pigmentation of legs noticed for one year. Has never taken medicine continuously for more than six weeks, and believes he has never taken

arsenic. He cannot explain the pigmentation, though at one time he stood in front of the fire for rather long spaces of time. There is now atrophy of both thighs, tibiales antici, ext. commun. digit. ped. peronei. Slight foot-drop, talipes equinus, and pes cavus. The sternal halves of both pectorals, the latissimi dorsi, teres major, subscapulares, and erectoræ spinae are wasted, and there is lordosis. The gastrocnemii are large. Although most of the muscles show A.C.C. > K.C.C. there are no other reactions of degeneration. Sensation is normal. The skin of legs is uniformly discoloured, and is a reddish-brown. Beginning above indefinitely, it becomes more intense, until it abruptly stops just above the ankle, where the tops of the boots would come. Below this level there are some scattered discrete patches of yellowish-brown pigmentation, with a few patches of rather a redder colour.

ERUPTION OF PSORIASIS TYPE BUT OF A SOMEWHAT UNCERTAIN NATURE.

Dr. J. A. ORMEROD showed a woman, *æt.* 39, married, who presented a peculiar rash of uncertain nature. It came out on the second day of a febrile attack in October last. She had been treated with liq. hydrarg. perchl. internally, and lotio nigra to the leg. The ulcers on the leg are nearly healed, the throat is no longer sore, and the face has improved a little; but in the rash as a whole there is no difference.

It was suggested that the eruption might be mycosis fungoides, and a committee was appointed to investigate and report thereon.

ATROPHIC PARALYSIS OF HANDS AND WRISTS, BEING THE REMAINS OF A RECURRENT GENERALISED PARALYSIS (? PERIPHERAL NEURITIS).

Dr. ORMEROD also showed a man, *æt.* 28, an ex-soldier, who was admitted to St. Bartholomew's, October 16th, 1901, with marked weakness and wasting of the upper limbs from the scapula downwards. In the lower limbs, some wasting of thighs, legs normal, knee-jerks feeble, plantar reflexes normal. No affection of sphincters, no affection of sensation. Electrical reactions normal, but feeble in some of the affected muscles. Has much improved, and the paralysis is now limited to the extensors of wrists and fingers, and the intrinsic muscles of the hands; but even these are better. This is the fourth attack of the kind. He had a chancre in 1893, slight malaria, but not enough to lie up, when in Bengal (this was prior to present illness); dysentery on voyage home (after present illness). There was no similar case in his regiment. The patient's urine darkens, after standing, to an intense brownish black. This appears to be due to some rare kind of pigment, which is under investigation by Dr. Archibald Garrod.

A FAMILIAR TYPE OF PARALYSIS ALLIED TO THE MYOPATHIES AND TO FRIEDREICH'S DISEASE.

Dr. F. E. BATTEN showed a girl, *æt.* 15, the eldest member of the family, who had always been weak on her legs, but during the past nine months she had become obviously weaker on her legs, especially in the peroneal and anterior tibial muscles, and in the extensors of the toes. There is foot-drop and pes cavus. The knee-jerks are absent, and the plantars cannot be obtained. No reaction to a strong faradic current can be obtained in the muscles of either leg, not only in the muscles obviously affected, but also in those not obviously weak. The arm muscles just react to a strong faradic current, and even the muscles of the face react badly. To galvanism there is no reaction to either the anodal or kathodal current in the anterior tibial peroneal or extensor muscles of the toes, but a slight contraction is obtained in the gastrocnemius. Four other children of the family on examination exhibited nervous abnormalities of a somewhat similar kind in a greater or less degree.

PROBABLE HYDROMYELIA IN A CHILD.

Dr. F. L. PENROSE showed a lad, *æt.* 6, whose head was small. Measurements: circumference eighteen and a-half inches; across from one external auditory meatus to the other twelve inches; from glabella to external occipital protuberance thirteen and a-quarter inches. Intelligence is apparently below normal. He is com-

pletely helpless to change his position; and if set up, his head falls forwards, so as almost to allow his chin to touch his chest; if unsupported he falls forward in a heap. He has never had any real incontinence of urine or faeces, but frequently has "accidents" owing to his not stating his wants clearly. The organs of special sense appear to be normal, and there is no paralysis of any cranial nerve to be detected. The diagnosis lay between the following conditions: (a) Hydromyelia or syringomyelia; (b) the infantile type of idiopathic muscular atrophy; (c) mental deficiency from microcephaly.

GENERAL PARALYSIS OF THE INSANE IN A CHILD.

Mr. C. H. FENNEL showed a girl, *et. 9*, whose father had syphilis before marriage, and died last year in Hanwell of paralytic dementia. The patient is the result of the third pregnancy, the first two having produced miscarriages; two healthy children were subsequently born. No definite history of congenital syphilis could be obtained; the child was mentally bright up to the onset of symptoms six months ago, when she gradually became apathetic and dull. Her speech is slurring. There is a congenital squint; the pupils do not react to light, and contract but feebly with accommodation. Bilateral optic atrophy is present with numerous patches of old retino-choroiditis. The facial muscles show intention tremor, and the tongue is tremulous on protrusion; the gait is hesitating and slightly ataxic. The knee-jerks are exaggerated; there is no sensory defect.

TWO CASES OF FILARIASIS,

one treated by a new operation, the other untreated.

Mr. RICKMAN J. GODLES (in the absence of Dr. Manson) showed a man, *et. 21*, native of Hayti, who came to England eight months ago with a view to treatment. He states that ten years ago swelling appeared in the right groin; later similar swelling appeared in the left groin; these have gradually increased to their present dimensions. Four times in the ten years he has had attacks of lymphangitis, during which the swellings have become tense, hard, and painful. The legs feel as if they would burst, and there is pain in the loins and abdomen, at the same time there is high fever and much suffering. These attacks, which he describes as "crises," may last for a month on end. He has had none for two years. In other respects his health is good, he can take exercise, and beyond the feeling of tension in the swellings and pain in the right loin, he is in good health. On inspection, two massive lobulated swellings occupy the upper part of Scarpa's triangle and the region of the inguinal glands. That on the left being about the size of three clenched fists, that on the right about half this size. From the lower border of the latter a dilated vessel can be traced downwards and inwards almost to the knee. The tumours are non-adherent to the skin, not freely movable, subfluctuating and doughy. They are irregular in outline, stand well out from the general plane of the thigh. On the patient lying down tension in the tumours is quickly relieved, and by pressure with the palm of the hand they may be made almost to disappear, on resuming the erect posture the swellings slowly return. They are dull on percussion. The patient's abdomen is unusually full for a youth of his age who is not over fat. He has never had chyluria nor any sign of elephantiasis. His blood contains rather a small stock of *filaria nectuma*.

The other patient was a man, *et. 31*, born in Calcutta, civil engineer, lived in India till 1898, then went to Gold Coast. *Filaria* discovered at the end of 1900, but has had slight swelling in groins for five or six years. The testicle (? scrotum) has also swelled. Patient was sent to him by Dr. P. Manson, Nov. 1901. He had a large swelling (varicose lymphatics) in right groin. There were a few *flaris* in the blood. On Dec. 4th at Dr. Manson's suggestion he cut down on the lower part of the tumour and with much difficulty anastomosed a dilated lymphatic vessel with a tributary of the internal saphenous vein. The fluid in the glands and lymphatics was a mixture of lymph and chyle. The result had been the almost complete disappearance of the lower part of the

swelling. The upper part of the swelling remained. In January, 1902, he anastomosed one of the dilated lymphatic vessels of the cord with one of the spermatic veins. The operation was easily performed. The lymphatics contained pure lymph. The swelling has diminished and apparently is continuing to diminish. It is probable that the obstruction to the thoracic duct is opposite the lymphatics accompanying the spermatic vessels, and thus, although there is an obstruction to the return of lymph from their radicles, there is no regurgitation of chyle.

ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF PATHOLOGY.

MEETING IN THE ROYAL COLLEGE OF SURGEONS,
ON FRIDAY, FEB. 21ST, 1902.

The President, Dr. E. J. McWENNEY, in the Chair.

Prof. E. H. BENNETT presented a cast and skiagraph of an example of fracture of the lower end of the radius with displacement of the lower fragment forwards (reversed Colles' fracture, Smith's fracture), and described the details of the injury which had occurred six months before its examination by him; he also discussed the treatment.

Professor E. H. BENNETT recorded the history of a case of impacted intracapsular fracture of the neck of the thigh-bone; he discussed the history, symptoms and diagnosis of the injury, and presented to the Academy a skiagraph which showed very fully the details of the bone lesion, a fracture in which the lower fragment was driven into the upper, and so by the impaction fixed the pieces in apposition.

Dr. KNOTT observed that the Irish school of surgery had now registered another of the many landmarks of the advance of osseous pathology which had been laid during a long series of years by Mr. Robert Adams, Professor E. W. Smith, and his successor, Professor E. H. Bennett. The fracture, which received its name from the great Dublin surgeon, had received its best and most apt illustrations from the author of the present communication. With regard to the fracture of the neck of the femur, Dr. Knott congratulated Professor Bennett on having secured a skiagram of impacted fracture of the neck. He would like to ask Dr. Bennett's explanation of the universal rule of non-union in cases of non-impacted intracapsular fracture of the femur. The direction of impaction in this case agreed with Professor E. W. Smith's rule that the neck always penetrated the other fragment.

Professor BENNETT, in reply to Dr. Knott's query, said he thought all surgeons were now agreed that the non-union of non-impacted intracapsular fractures was due to want of contact of the fragments and want of rest of the part. In all the specimens he had seen the lower fragment was impacted in the upper.

Professor Bennett, having been called to the chair, Professor E. J. McWENNEY, M.D., read his paper:—

CULTIVATION OF THE TUBERCLE BACILLUS ON LOEFFLER'S SERUM DIRECT FROM THE HUMAN SUBJECT.

He demonstrated a case of tuberculous pleuro-pericarditis in which the bacilli were unusually numerous, so that cultures made direct on Loeffler's serum gave abundant growths. He exhibited these primary cultures, showing the lichenoid appearance of the colonies, and their characteristic tendency to grow on to the glass. Secondary cultures on glycerinated potato were also shown. They were most luxuriant, of a light reddish hue, and the bacilli formed a corrupted scum on the dilute glycerine below the constriction in the tube. He also exhibited tertiary cultures on glycerine agar which were succeeding well. On this medium the colonies were whitish. The case was one of much interest. Patient, a male, *et. 55*, had a left tuberculous pleurisy. In the right lung were nodules of tuberculous broncho-pneumonia, but the pleura was free. The superior pericardial glands were tuberculous, and the parietal layer of the pericardium was much thickened and infiltrated with caseous matter. The visceral layer was normal, save for a single

spot on the anterior surface of the heart, where a slight roughness indicated that the process had begun to extend owing to friction with the parietal layer. The spleen was much enlarged so as to form a tumour readily palpable during life. It was studded with yellowish necrotic masses larger than miliary tubercles, and containing tubercle bacilli in large numbers. The kidneys and liver were likewise studded with minute necrotic foci, entirely devoid of giant or epithelioid cells, but remarkably rich in tubercle bacilli. Sections of these were shown, and the speaker pointed out that this was an example of the inverse ratio so often remarked between the number of the bacilli and the toxicity of the tuberculous structure. In the affected parts of the pericardium the bacilli formed masses large enough to be seen with the low power in the stained preparation. The affection of the spleen, kidneys, and liver was doubtless to be regarded as the result of a terminal inundation of the blood stream. There were appearances on the *intima* of the aortic arch where the tuberculous pericardial glands were adherent to it, that seemed to indicate that the rupture might have taken place into that vessel. But as yet he had not proved this microscopically. He concluded by adverting to the frequency of this form of pericarditis, which was pointed out by Osler, and stated that since his attention had been called to the matter he had found it very frequently in the *post-mortem* room.

The President also showed a specimen of Colloid Cancer of the Cæcum that had occurred in an elderly woman.

The President, having again taken the chair, called on the Secretary of the Section to read Dr. Rambaut's paper, "A Case of Congenital Hydronephrosis," which will be found on page 239.

Dr. McWENNEY from the appearance of the specimen exhibited said he would be slow to describe the case as one of pure hydronephrosis. To him it appeared to be a case of dilatation of the pelvis, and calyces of the kidney, rather than one of hydronephrosis.

On being called on to read his paper on Hypertrophic Cirrhosis of the Liver, Dr. W. J. Thompson informed the Academy that with the permission of the President of the Section, his paper on the subject was held over to allow of a more exhaustive examination of the specimen. He then read his notes on a Huge Abdominal Cyst, which will be found on page 237.

Dr. E. J. McWENNEY said that his extremely interesting cyst was preserved unopened on his (Dr. E. J. McWenney's) advice. It was a good illustration of the rapid growth to an enormous size that pancreatic tumours, or tumours connected with the pancreas, may attain. Some time ago he exhibited to the Section a tumour which, before removal, he looked on as of pancreatic origin, but on dissecting it out he found that, although the pancreas was attached to, and might be said to form a part of its posterior wall, it was a hæmatoma of the lesser peritoneal cavity, with walls, such as one found in large aneurysms, of organised blood-clot.

The meeting then terminated.

HARVEIAN SOCIETY OF LONDON.

MEETING HELD AT STAFFORD ROOMS, TITCHBOENE STREET, W., ON THURSDAY, FEB. 20TH, 1902.

Mr. WATSON CHEYNE, F.R.S., President, in the Chair.

CLINICAL EVENING.

PSORIASIS AFTER VACCINATION.

Dr. WHITFIELD showed a young woman, the subject of psoriasis, which came on fourteen days after vaccination. The vaccination marks on the left arm were very severely affected, the right arm being more or less clear. The chest and back and knees and shins also showed the condition. He had not previously noticed such a strong tendency for the condition to affect the vaccinated arm as in this case, and he had no theory to advance to account for it. He was using creosote, which was especially useful in acute cases.

CASE OF CONGENITAL HEART DISEASE.

Dr. MORISON showed a boy, æt. 5, the subject of congenital heart disease, there being an abnormally placed heart, giving a considerable amount of dulness to the right side of the sternum. The second sound was felt by the hand very clearly over the precordial region, and very clearly indeed to the right of the sternum. There was a systolic bruit, which gained in intensity towards the pulmonary area, and was very loud over the front of the chest. It was also propagated very widely over the back and flanks. It was also audible in the neck, and it was sometimes mentioned as a diagnostic point that if a bruit of that description was audible in the neck, there was some defect involving the base of the aorta as well as the pulmonary artery. His own belief was that in the present case there was pulmonary constriction.

Dr. CALVEY thought there must be pulmonary stenosis in the case, because of the features of the bruit and the hypertrophy of the right ventricle; possibly there was in addition an incomplete intra-ventricular septum.

Dr. CAUTLEY pointed out that there was no thrill, and his own experience was that pulmonary stenosis was much more commonly diagnosed ante-mortem than post-mortem. He referred to the case of a child who during life had practically no cyanosis, had a systolic murmur all over, and subsequently was found to have atresia of the conus pulmonalis. The orifice was so narrowed that it would only admit a fine probe, yet there was no cyanosis. There was, in addition, a patent septum ventriculorum. That led to the question as to the cause of cyanosis.

Dr. MORISON, in reply, said he did not feel certain that the stenosis in the case was a tight one.

CASE OF BAZIN'S DISEASE.

Mr. H. L. BARNARD showed a young woman, the subject of Bazin's disease, who has had the ulcers on her legs for the last five years. They appeared first as nodules under the skin, and felt something like erythema induratum. Those burst and broke down and formed little round ulcers about the size of a shilling, punched out, and extraordinarily like specific ulcers, for which they were often mistaken. They were supposed to be tuberculous, and he regarded the present patient as tuberculous. She had had tuberculous disease of the spine and of the left ankle, the latter having got well after being put into a plaster of Paris case. The ulcers left a pigmented scar which looked extremely like that left by a specific ulcer. The patient was very subject to chilblains.

Mr. CAMPBELL WILLIAMS thought there was no doubt about the diagnosis, but one point about the case was abnormal, namely, its asymmetry. In his original description of the disease Bazin said he had never seen it extend above the knee. That was obviously wrong, because it was not only there, but might be limited to that region. Recently he saw a lady who had a patch on either knee, on the vastus internus, the lower part of the limb being free. It might occur on the hands. The present case was typical, because it had ulcerated. Occasionally resolution occurred without ulceration, leaving a fawn-coloured depression. The lesions were often mistaken for tubercle, but more frequently for syphilis, the patient being dosed with iodide of potassium. When the condition did not get well under that, it was found that treatment by tonics, cod-liver oil, and warmth, with antiseptic dressings to keep the part clean, did much good. If the patients could go to a warmer climate they got rapidly well.

Mr. EDDOWES said most of such patients had a good deal of standing, and a fair number of them were washer-women. The condition was worst in the winter, indeed it occurred in some cases only in the winter. Mercurial ointments and pressure to the legs were of great benefit.

Mr. BARNARD, in reply said that he put the girl upon a good course of iodides and mercury, but the original ulcers got well under treatment by strapping with Scott's dressing. The last crop of lesions had got well under boric acid ointment with bandaging, combined with a tonic.

Mr. BARNARD showed a girl with an anomalous con-

dition of the hand, and asked for opinions upon it. She came three or four months ago for what was regarded as an erysipelas rash, though he did not know whether at that stage it was erysipelas or cellulitis. The vesicles came up at night, then burst and left linear marks. It was interesting to notice that the marks were upon the left hand and in a direction from right to left. When first seen they were symmetrically arranged, and in almost a mathematical pattern. He thought no one who saw the case doubted its artificial origin. The girl was left-handed.

Dr. CAMPBELL WILLIAMS said the case was about the most typical one of dermatitis factitia which had been produced before this or any other society.

Dr. EDDOWES related the case of a woman who, by means of an elastic band placed around her arm near the axilla, produced an enormous swelling, and as a result allowed a surgeon to make five incisions, under the belief that it was a case of phlegmonous erysipelas. The next stage contemplated was amputation. He was able to stop that by telling the patient how the swelling had been produced, and obtaining the band by means of which it was done.

CASE OF SYRINGOMYELIA.

Dr. JAMES TAYLOR showed a young woman suffering from syringomyelia, whose history will be found under "Clinical Records."

Dr. MORISON, the President, Mr. BARNARD, Dr. CANTLEY and Dr. DALLOWAY took part in the discussion.

OBSCURE AFFECTION OF THE NAILS.

Dr. EDDOWES showed a schoolmaster, *et. 23*, who suffered from separation of the nails. The man for nine months found a tendency for his nails to separate, but there was no other indication of disease about him. There was no indication of psoriasis. The nails had been carefully examined for a fungus or other parasitic cause, but with a negative result. There was not the ordinary appearance of a disease such as ringworm or favus. He invited suggestions as to treatment and cause.

Dr. PHILLIPS said he had never seen an exactly similar case, but a somewhat analogous condition had existed in his own person in the big toe nails of both feet. For many years the inner three-fourths died, and he had to cut that portion away. Underneath was a horny, pulpy matter, which he also cut away. He suffered from bad circulation, and attributed it to that, combined with a neurotic origin. Both his hair and his nails were of very slow growth.

Dr. EDDOWES also showed a nurse who presented a swelling in the right forearm, which appeared to have been aggravated by sewing. Sometimes she complained of a good deal of pain and tenderness.

Dr. BOYD JOLL suggested that the condition might be neuroma or neuro-fibroma. There was a diffuse swelling under the skin, which he thought was separated from the muscle.

Mr. LONGBRIDGE suggested the possibility that it was phantom tumour of the muscle. He suggested anæsthetising the present patient to see if the tumour disappeared.

Mr. CAMPBELL WILLIAMS said one sometimes saw a nævoid condition occurring in muscle which might be quiescent for many years and then take on activity. The patient pointed out that the tumour got better when the arm was in a certain position, namely flexion. It was unusual for that muscle to be affected by nævoid growth. There were many points in the case against tubercle and specific disease. It had a different feel to gummatous myositis.

The PRESIDENT thought the tumour was muscular. He had seen a similar tumour mistaken for neuro-fibroma.

Dr. EDDOWES said his first impression was that the condition was a muscular swelling, and probably the special exercise coming on after prolonged rest might have been sufficient to cause it. But she had good movement in the hand, and he could find no indication of paralysis or weakness. He once saw the forearm of a man very tender and hard, following a new occupation—namely, milking. A few weeks of the work left

him so exhausted that he could not pick a penny off the table. The tumour was smaller than a fortnight ago.

AURAL EXOSTOSIS WITH MASTOID DISEASE.

Dr. TILLEY showed a girl, *et. 14*, who had an aural exostosis with extensive mastoid disease. She came to hospital because she had some obstruction in the right ear passage. When first seen there was no discharge, but the occlusion was so great that the finest probe could not be passed into the auditory meatus. Last August some post-nasal growths were removed, and some weeks afterwards a moist discharge came from that ear. To get rid of it he reflected a post-aural flap, as in the mastoid operation, in preference to trying to burr away the growth through the auditory meatus. There was no difficulty in gouging out the broad-based exostosis. He found the passage full of inspissated pus. That was cleared away, and the tympanic region reached. The ossicles were not to be found. He thought it better to look into the antrum to see if it was clear, because he could pass a probe from the end of the passage to the antrum. The antrum was full of the same inspissated material, and it extended halfway down the mastoid. That was cleared out and the complete post-aural operation was done. The external wound was sewn up and the packing done through the meatus. The membranous portion of the meatus was slit up, and the flap made in the usual way. The wound healed at the back by first intention. A fortnight later he reopened the wound and produced a clear surface by scraping away the granulations and putting in a large flap from the inside of the thigh, after the method introduced by Mr. Ballance. The skin graft had taken there, and there was practically a dry cavity. She was now able to hear a whisper at four inches, and the hearing was fairly good considering what had been done and that she had no tympanic membrane nor ossicles. He showed the case to illustrate what extensive disease could be present without symptoms. He could get no history of earache or headache, or anything which would lead one to think there was trouble behind the ear. It was easy to see that if she had an attack of influenza or one of the acute specific fevers there would have been very serious trouble.

CASE OF ABDOMINAL ANEURYSM.

Dr. CALVEY showed a case of abdominal aneurysm in a man, involving the aorta and the right common iliac. His age was 39, and he came to the surgical out-patient department in January, 1900, on account of a varicose condition of the veins of the left leg and thigh. When first seen there was a large pulsating tumour commencing three inches above the umbilicus, and extending along the course of the right common iliac artery. The right margin of the tumour was well-defined and hard. There was marked expansile pulsation, and on pressure a slight systolic thrill and bruit. There was no perceptible pulse in the right external iliac or femoral arteries, but exaggerated pulsation in left external iliac and femoral arteries. With prolonged rest in bed, restricted diet, and potassium iodide (*gr. xx t.d.s.*), the pulsation much diminished in extent and in degree, the tumour became more solid, and the distension of the veins of the leg almost disappeared. For the last eighteen months the improvement has been maintained, and for some months past he has been able to resume his work. The chief points of interest are, the absence of pain, the considerable vertical extent of the arterial lesion, and the degree of improvement under strict treatment.

Mr. BARNARD said a man at the London Hospital had a superior mesenteric aneurysm which was twice published as an example of cure by different treatments. In the first place it was said to have been cured by gelatine treatment. Then it relapsed and was treated with antiphtheritic serum, and was cured under that. Now, three years afterwards, it was in the London Hospital again, being treated with morphia, and it was suggested that the surgeon might like to ligature it. But the risks were too great for the man to consent to run them, and he would not allow a wire to be introduced into the sac.

Dr. CALEY, in reply, said there was a clear history of specific trouble fifteen years ago, but no history of injury.

LIVERPOOL MEDICAL INSTITUTION.

RUSHTON PARKER, M.B., F.R.C.S., President, in the Chair.

CEREBELLAR ABSCESS WITH THROMBOSIS OF THE LATERAL SINUS.

MR. DAMER HARRISSON described a case in a young man, who had suffered from ear disease for eleven years. There was some dulness of the intellectual faculties, paresis of the right facial nerve, with a tendency to fall to the right side. There was some swelling over the mastoid process, and fulness in the upper part of the neck. No optic neuritis. The antrum was cleared, the necrosed inner wall removed, and the abscess cavity opened up. The patient became very collapsed, and further operation was deferred. After a few days the temperature being still irregular, the internal jugular vein was exposed, and ligatured below the thrombus, an excised bit of vein contained a softening clot. Patient made an excellent recovery.

MR. C. G. LEE had seen some thirty cases of cerebral and cerebellar abscess, resulting from ear disease. In many cases it was often impossible to say in which situation the abscess was. Optic neuritis, Mr. Lee said, was as frequently absent as present in cases of cerebral and cerebellar abscess. Cerebral abscesses were frequently multiple, and Mr. Lee referred to the case of a child who had paralysis of one arm and leg, and in which he opened and evacuated the abscess. This was followed by complete recovery of the limbs. Ten days later the child died, and the post-mortem showed the whole of one occipital lobe necrosed, and several small abscesses scattered about the cerebrum.

Dr. PHILIP NELSON asked if the source of the discharge from the ear had been definitely ascertained, for, owing to difficulty of drainage, mastoid and other complications were more liable to occur when the attic was the seat of the trouble, the perforation being in the m. flaccida. Referring to the facial palsy, Dr. Nelson pointed out the frequency of this trouble in tuberculous disease, particularly in children.

The President, Drs. Permewan, Grünbaum and Mr. Murray spoke, and Mr. HARRISSON replied.

CÆSARIAN SECTION TWICE, EMBRYOTOMY ONCE, IN THE SAME PATIENT.

Dr. NATHAN RAW showed a woman, upon whom he had twice performed Cæsar section. There was no evidence of rickets. The conjugate diameter of pelvis was 2½ ins., the promontory of the sacrum projecting markedly. At the time of the first section the patient had been twenty-six hours in labour, and general cutaneous emphysema was present. The child from the second section was shown, and attention drawn to the circular shape of the head. Dr. Raw raised the question as to what the correct procedure was in this case. The patient was unmarried. He thought she must take the consequences, but it was a most difficult question to answer.

The President, Dr. Moffe Campbell, Dr. Briggs, Messrs. Paul, Harrison and Newbolt spoke, and Dr. RAW replied.

X-RAY AND FINSEN TREATMENT OF LUPUS AND RODENT ULCER.

Dr. DAVID MORGAN showed three cases of very obstinate and extensive lupus and rodent ulcer cured by the X-rays and violet light. The first case, a woman, æt. 34, had suffered from childhood with lupus of the nose and cheeks. Every variety of surgical treatment had been adopted, including over forty scrapings, but the benefit was only temporary. X-ray treatment had proved quite successful, the patient exhibiting a very healthy white scar. The second case was a tuberculous ulcer of the cheek of limited size treated by the violet rays. A healthy cicatrix formed in six weeks. The third case was a large rodent ulcer over the scalp and forehead in an

elderly spinster. The disease had been in progress for many years and was too extensive for excision. Three months' treatment with X-rays had cured the disease.

Dr. FRANK H. BARNETT thought that the results produced by the X-rays and light treatment in Dr. Morgan's three cases had been unattained by any method hitherto practised. The case of healed serpiginous rodent ulcer of twelve years' duration showed an excellent result. No previous treatment had any permanent effect, and now the former site of the ulcer was occupied by a smooth and, to the naked eye, sound scar; moreover, there was a total absence of any return. The dermic results of the X-ray and light treatment could not at present be explained; it was futile to theorise about their therapeutic effects in the absence of definite knowledge of the nature of the rays which have produced such remarkable results as portrayed in these cases.

Dr. STOFFORD TAYLOR congratulated Dr. Morgan upon his interesting and instructive demonstration. He said the effect of the "light" treatment was largely superficial, and the number of cases to which it could be applied were limited in numbers on account of the necessity of actually placing the lamp in contact with the surface. With the X-rays it was quite a different matter as they certainly penetrated much more deeply, and can be therapeutically applied to every part of the body.

Mr. ARTHUR WALKER mentioned that Dr. Finsen had found Bang's iron electrode lamp unsuccessful in the treatment of lupus on account of the lack of penetration of its rays.

The President and Mr. PAUL emphasised the need for microscopical confirmation of the diagnosis. Drs. Permewan and Holland also spoke, and Dr. MORGAN replied.

THE PREPARATION OF THE HANDS FOR SURGICAL OPERATIONS.

Dr. GRIMSDALE described the method he had used for some time. The hands were cleaned with a nail brush and boiled water for a definite time, then soaked in a solution of potassium permanganate, the colour was discharged by washing in oxalic acid solution, the acid neutralised by washing in sterilised lime water, and finally the hands were washed in sterilised water. The results of this method had been rigorously tested on several occasions by Drs. E. E. Glynn, Abram and Hill. In every instance Dr. Grimsdale's hands and those of his assistants were sterile, and in his opinion, therefore, the hands can be made practically sterile. Moreover, of all the methods he had tried this one had the least roughening action on his skin; in fact, it did not roughen it at all. He did not think the method was simply mechanical in its action.

The President, Drs. Briggs, Hill, Grünbaum, Messrs. Harrison, Paul and Hawkins-Ambler discussed the paper, and Dr. GRIMSDALE replied.

THE GENERAL MEDICAL COUNCIL OF EDUCATION AND REGISTRATION. SPECIAL SESSION.

SIR WILLIAM TURNER, President, in the Chair.

TUESDAY, FEBRUARY 25TH, 1902.

THE Special Session of the Council was inaugurated on Tuesday by the President, who recalled that a committee had been appointed at their last session to report on the differences that had arisen between certain licensing bodies and the Council in respect of the courses and conditions of study and the recognition of the institutions and schools in which the required courses might be taken. It was to consider the report of this committee that the Council had been called together.

Before proceeding to do so, however, the Council gave precedence to the Midwives' Bill, which was down for second reading in Parliament on the following day.

Dr. ATTHILL moved that the Council should adhere to its previous resolutions in regard to the Bill, and that the Lord President of the Privy Council should be informed that in the opinion of the Council the provisions of the Bill were at variance in several important respects with the principles adopted by the Council, and do not embody the safeguards for the protection of the poor which the Council regarded as essential; and urging that the Bill as now before Parliament should not be allowed to become law.

The resolution, with sundry modifications, including the insertion of the words, after Bill, "in its present form," was agreed to after some discussion; and it was further agreed, on the motion of Mr. VICTOR HOESLEY, that in the event of the Bill passing the second reading Sir John Tuke be requested to communicate the Council's resolutions to the Grand Committee on Law.

The Council then took into consideration

THE REPORT OF THE SPECIAL COMMITTEE ON THE CURRICULUM.

The Report having been received and entered on the Minutes subject to certain modifications, its adoption (leaving the recommendations over for subsequent consideration) was moved by Dr. McVAIL.

The Committee's conclusions are as follows:—

I. The Medical Council has decided that the scientific institutions other than Universities or recognised medical schools, at which the courses of study in chemistry, physics and biology may be taken by students as part of their medical curriculum, are to be approved by the Medical Council prior to registration in the *Students' Register* of students commencing their studies at those institutions.

II. The Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England, notwithstanding repeated remonstrances made to these Colleges by the Medical Council, continues to recognise courses of study in a large number of teaching institutions that have not been approved by the Medical Council, and does not now require registration in the *Students' Register*, nor that the students should have passed a preliminary examination recognised by the Medical Council, but a preliminary examination the recognition of which is determined by itself.

III. The Conjoint Board of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Faculty of Physicians and Surgeons of Glasgow, although requiring evidence that candidates who present themselves at their first professional examination, which includes the subjects of physics, chemistry and biology, shall have been registered in the *Students' Register*, and thus must have taken the courses of study in these subjects at institutions which have been approved by the Medical Council, nevertheless admits candidates to its second and subsequent professional examinations when such candidates produce evidence that they have passed the first professional examination of the Conjoint Board of England, and the regulations of the Scotch Conjoint Board do not require in such cases evidence that the courses of study in chemistry, physics, and biology undergone by such candidates have been so undergone at scientific institutions which have been approved by the Medical Council.

IV. The Society of Apothecaries of London, although requiring evidence that candidates who present themselves at its first professional examination, which includes the subjects of chemistry, physics and biology, shall have been registered in the *Students' Register*, and thus must have taken the courses of study in these subjects at institutions which have been approved by the Medical Council, nevertheless admits candidates to Part II. of its primary professional examination when such candidates produce evidence that they have passed the first professional examination of the Conjoint Board of England, and the regulations of the Society of Apothecaries do not require in such cases evidence that the courses of study in chemistry, physics and biology undergone by such candidates have been so undergone at scientific institutions which have been approved by the Medical Council.

V. The University of Oxford prescribes practically no curriculum of study to be undergone by candidates previous to their admission to the professional examinations conducted by that University for its degrees in medicine, nor does it require candidates to have been engaged in medical study for any definite minimum term of years, and it does not require evidence of registration in the *Students' Register*. It asks only that candidates for its second or final examinations for the M.B. degree "must present certificates of instruction in infectious diseases and mental diseases, and of attendance in labours and of proficiency in the practice of vaccination."

VI. The University of London admits candidates to its Preliminary Scientific Examination, which is one of the examinations for the medical degree, altogether irrespective of evidence of study in these subjects at any scientific or teaching institutions. As regards the remaining subjects of the medical curriculum the University of London requires evidence only that five of eleven subjects which it enumerates shall have been taken in Universities, Schools of Medicine and Hospitals approved by it. The University does not require evidence of registration in the *Students' Register*, but it does require that candidates for its medical degrees shall have been engaged for five years in medical study subsequently to their having passed their matriculation examination, and four years subsequently to having passed the Preliminary Scientific Examination.

Dr. McVAIL said the report would open the eyes of

many members of the Council to the widespread non-conformity of various licensing bodies with the principles which it was the right and the duty of the Council to maintain, and he expressed surprise that the Council should not have taken cognisance of the fact long before. He maintained that the Council had a perfect right to indicate what the minimum should be, and if it were decided that certain courses of study now being pursued were insufficient, they would have to take the matter to the Privy Council. If not, within twelve months, each body would be doing just what it pleased, and the function of the Council in supervising medical education would be at an end.

Dr. YOUNG seconded.

Dr. NORMAN MOORE, on behalf of the Royal College of Physicians, protested that unless the Council investigated the whole subject, it had no right to assert that a secondary school was not a suitable place for imparting scientific instruction. The College had inquired into the matter and had inspected the schools, and they had no apprehensions concerning a possible reference to the Privy Council. He asked whether it was really asserted that the University of Oxford and the Royal Colleges had been granting the right to practise to persons who had not the requisite knowledge and skill.

WEDNESDAY, FEBRUARY 26TH, 1902.

SIR WM. TURNER IN THE CHAIR.

Dr. PAYNE, representing the University of Oxford, expressed surprise that after the lapse of so many years it should suddenly be proposed to pass resolutions which would render it necessary for the Council to take action against the bodies concerned, and he warmly defended the University which he represented against the imputation of admitting to graduation men not efficiently trained.

Sir CHRISTOPHER NIXON doubted whether the points which had been raised in reference to the recognition of certain institutions for the teaching of preliminary scientific subjects were of sufficient gravity to make a representation to the Privy Council necessary. How, he asked, could the Council know whether these institutions were defective or not. He urged that they might well be content provided a certain minimum of education were maintained, and pleaded for abstention from any interference which would arouse hostility and ill-feeling.

Mr. THOMAS BRYANT challenged the power of the Council to enforce all its edicts and pointed out that after all they could only issue "recommendations." He suggested that the Council would be wise in adhering to the lines hitherto followed which had led to much good work. He thought they would run the risk of forfeiting some of their political power if they appealed to the Council on such a manner.

Dr. HERON WALTON congratulated the Committee on the task it had accomplished, but said that Dr. McVAIL was in error in asserting that the Scotch Board accepted the grant of the English Conjoint Board without question. That was not the case. Their policy in Scotland was to recognise only institutions and private teachers under their own auspices, and they invariably inspected the premises and apparatus for teaching, but they certainly recognised institutions which were recognised by the Conjoint Board in England and Ireland, no other course being open to them.

Sir HUGH BRVOR said that the Society of Apothecaries only in the most indirect way recognised institutions not adopted by the Council.

Sir HECTOR CAMERON thought the non-conformity of the Conjoint Board was more apparent than real. Their position was what it had always been.

Mr. YOUNG hoped the report would be adopted.

Dr. MACALISTER discussed the legal argument with regard to the procedure of the Privy Council, and pointed out that the General Council could alone be heard by the Privy Council.

Sir WILLIAM GAIRDNER was strongly opposed to any appeal being made to the Privy Council.

After some desultory discussion the motion was carried by 17 to 4.

THE RECOMMENDATIONS.

Dr. McVAIL admitted that there might be a difficulty in getting the Council to pass the recommendations, and suggested an alternative which, it transpired, had already been embodied in a motion by Dr. MACALISTER to the effect that the Examining Board in England be required to furnish the Council with certain details regarding the courses of study in chemistry, physics and biology to be gone through by candidates for the L.R.C.P.Lond., and M.R.C.S.Eng.

Dr. McVAIL seconded the resolution, adding that the original recommendations had not been withdrawn; they were simply not moved. It was urged, however, that if they were not to be moved they ought to be formally withdrawn, and after a sharp discussion this was done, and Dr. MacAlister's resolution was agreed to.

MIDWIVES BILL.

It was announced that the Bill had been read a second time, and the names of Sir John Williams and Mr. G. Brown were added to the committee to watch its further progress.

The Special Session concluded with a vote of thanks to the President for his able and courteous conduct in the chair.

Lunacy Department.

PROPOSED PSYCHIATRIC WARDS IN THE
EDINBURGH ROYAL INFIRMARY.

AN important step towards the furtherance of this most desirable object was taken on the 20th ult., when a special meeting of the Medico-Chirurgical Society, attended not only by the members of that society, but also by a number of the Infirmary managers, members of the Board of Lunacy, and several prominent citizens, was held to discuss "the treatment of incipient and transient mental disorders in the infirmary." The chairman explained that the subject had been brought forward by Dr. John Macpherson, Commissioner in Lunacy, and Sir John Sibbald, who formerly held that office. They had in the first instance to define what kinds of mental disorder might be beneficially and properly healed in the infirmary, and also to let the public know what accommodation was required, how many cases were proposed to be treated, what the probable cost would be, and in what respects treatment in the infirmary would confer benefits on the patients and the public. Sir John Sibbald opened the discussion by indicating the twofold defects of the present methods of dealing with insanity, first in the treatment being limited (so far as the poorer classes of the community are concerned) to that in asylums, with its inevitable stigma; and second, in the teaching being limited to clinics on cases which were so far advanced as to be certifiable. Little was needed to show that the wards would be useful from a charitable point of view, as patients in the early stages of insanity were almost entirely neglected at present, and a considerable number of persons were thus allowed to fall into incurable insanity who should have been saved from that fate. That many cases of incipient insanity could be successfully treated in ordinary general wards was fully demonstrated by the great benefit which asylum physicians now found to accrue from treatment by rest in bed and careful nursing. It was found in asylums that the bulk of the nursing in male wards could be entrusted to female nurses, and the modes of treatment, massage and hydrotherapy, which, combined with rest in bed, had proved of greatest service in asylums, were all such as could be readily applied in general wards. The wards would in no way differ from the ordinary hospital ones. This was of the greatest importance in order to avoid every suggestion of an asylum and to impress the patient and his friends with their true character as a part of an institution whose object was the cure of physical disease. In regarding as suitable wards which did not differ from those of a general hospital, it must be borne in mind that neither compulsory detention nor a long period of residence on the part of patients was intended. Personally, he would be satisfied by a limit of six weeks.

He then pointed out how in this country we were behindhand in our clinical teaching, and that psychiatric wards formed a part of every medical school in Germany, whereas here the ordinary student received no instruction whatever on the treatment of incipient mental disorder. The Master of Polwarth, Chairman of the General Board of Lunacy, said that it had been the policy of the Board to encourage every new movement which seemed likely to conduce to the benefit of those who had the misfortune to suffer from one of the most terrible forms of disease. He could assure the meeting that they would look with a sympathetic eye on any such scheme as this, which would remove the stigma attaching to mental disease, and which would, he hoped, by curing the patients before their malady had advanced, relieve the ratepayers of what was daily becoming a heavier burden. Sir John Batty Tuke expressed his satisfaction at the practical shape which the proposal was taking. He had preached this doctrine in season and out of season for twenty years, and when the infirmary buildings were in process of erection, Sir Arthur Mitchell made a strong effort to get wards such as those proposed, but even his great influence failed. The scheme would reduce the number of lunatics, and would exercise a widespread educational influence. The burden on the rates was due to the chronic lunatic, and whereas money was now poured out to take care of him, not a penny was spent in trying to prevent incipient cases progressing to that stage. His belief was that if they excluded general paralytics and epileptics, and treated cases in the earlier stages they would get 70 per cent. of recoveries. The increase of chronic lunatics was not in the upper classes, who could afford early and efficient treatment, but among the poor, who could not. Above all, the gradual education of the public mind would rapidly do away with the stigma attached to insanity, which had no more right to attach to it than to any other form of disease. Dr. Clouston mentioned that of 900 admissions to Morningside Asylum, only 80 were discharged within six weeks, and 160 within 2½ months. This pointed strongly to the conclusion that it would be a very economical thing for the parish council to come to some business arrangement with the infirmary to treat incipient cases, and thereby prevent the rates being burdened by their becoming chronic. He estimated that about forty beds would be necessary. Drs. Bruce and Affleck, speaking as physicians to the infirmary gave their hearty support to the scheme, the latter pointing out certain difficulties as to site, which, however, he did not regard as insuperable. What was, however, in many respects, the most convincing speech of the meeting was that by Dr. Carswell, adviser in lunacy to the Glasgow Parish Council, who was in the fortunate position of being able to advance the most effective of all arguments—that of facts. For a scheme has been in operation in Glasgow for several years, and is now about to be put on a permanent footing, for the treatment of insanity in its early stages, and a mental block for fifty patients is now being erected in connection with one of the poorhouse hospitals, where patients will be treated on hospital lines. Last year, in temporary and smaller premises, 212 patients were treated; of these, twenty-eight were afterwards removed to asylums, ten died, seven remained under treatment at the end of the year, and 167 were discharged recovered. These were all patients who applied to the parochial officers for certification in the usual way, and nearly all would, but for the existence of the wards, have been certified and sent to an asylum. With better facilities he hoped to pass not less than 300 cases of mental disorder through the ward annually—that is, about one-third of the total applications made in the Glasgow parish with its population of close on half a million souls. He hoped also to establish an out-patient clinique.

The discussion was most hopeful from a medical point of view, but, considering that so many laymen attended the meeting, it was a little to be regretted that the proposals were not more clearly explained. That misconception existed was shown by one of the lay infirmary managers asking what amount of ground would be required, he being evidently under the impression that

the statutory area required for asylums would have to be given by the infirmary. It was not made sufficiently plain, either, that no certification of patients was necessary, while perhaps a little too much was made of the educational advantages which the wards would afford to medical students. It seems a pity that none of the speakers had come prepared with the facts and figures as to recoveries in foreign clinics, for one cannot but remember that if the scheme is to come to anything it must rest on a demonstrable benefit to the public. Again, the physical nature of insanity might have been more strongly insisted upon, and the fact that modern physicians depend almost entirely on ordinary therapeutic measures. It seems clear that to carry out any such scheme the main argument must be that insanity is a disease like any other, and in many cases responds like any other to rest and nursing; that it is the one and only disease in which the poor man is *absolutely* deprived of the benefits which wealth affords his more fortunate brother, and that there is no reason whatever, save conservatism, and use and wont, why a hospital should refuse its help to incipient cases of insanity, any more than to early cases of cancer. As secondary arguments we should place the immense educational advantage which would accrue if the lay mind could be persuaded that the insane are not the subjects of demoniac possession, and that a man who has once been insane is no more a suspect than he who has had pneumonia; and subsidiarily, the ultimate relief to the rates by the cessation of a system which manufactures chronic lunatics. Finally, we would place the argument from clinical teaching. But this, as Dr. Bruce rightly said, is of minor weight. The wards in which clinical teaching is most actively pursued are those in which the patients are most carefully examined and most thoroughly treated. Only one point in the proposal requires mention—that is, as to which would be the most suitable medical officer for such a ward, an alienist or a general physician. The subject is a delicate one, and rightly did not occupy the meeting, the only expression of opinion being that of an asylum superintendent, who said that the superintendent of an asylum ought to have no time for such work, and that the post should be filled by a physician, or at least should be entirely separate from any asylum appointment.

CHLOROFORM AND HEART AFFECTION.

At the meeting of the Académie de Médecine M. Guyon spoke on the subject of chloroform as an anæsthetic on persons suffering from heart disease, and said that he at least found that in such persons chloroform was well tolerated. Consequently he arrived at the same conclusion as that of MM. Huchard and Bucquoy, which was that chloroform was not more dangerous in individuals with heart disease than with others. However, he would make certain reserves in cases of fatty *dégénérescence*, for it was, in his opinion, to that affection of the myocardium that two of his patients succumbed on the operating table. Yet he did not pretend that chloroform was exempt from danger; on the contrary, he considered that it should be closely watched. There was no necessity to give large doses; small quantities were attended with less danger, and were sufficient to produce the desired result. The respiration of the patient was at all times the object of much solicitude on the part of the operator, but the pulse should not be forgotten, especially in the third stage of the anæsthetic; if it became small, rapid, and irregular danger was at hand.

M. Brouardel said that out of twenty-five post-mor-

tems he practised on persons who died under chloroform not one presented any signs of valvular disease; three of them had the heart loaded with fat. In all the other cases the fatal termination was attributed to cardiac syncope. Amongst the lesions discovered at the autopsies he would mention the relative frequency of renal disease, yet he did not consider that they constituted a counter-indication to the administration of chloroform. It should be borne in mind that the use of anæsthetics had not created a new form of death by inhibition of the heart or of the respiration; the danger was not from the mode of administration of the anæsthetic, but frequently from the susceptibility of the patient.

The same subject was treated at the Société de Chirurgie. M. Tuffier said that he lost a patient he was about to operate for anal fistula, but he could not incriminate the quality of the anæsthetic. The arrest of the respiration preceding always that of the heart, it was necessary to stop the administration of the chloroform as soon as the respiratory rhythm became irregular; the practice of artificial respiration was generally sufficient to revive the patient. On the other hand, we were disarmed against cardiac syncope.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 1st, 1902.

At the Free Society of Surgeons, Hr. v. Bergmann made some remarks on

GUNSHOT WOUNDS OF THE HEAD.

He had several times pointed out that in time of peace gunshot wounds of the head made with small bullets, 5 to 9 mm. were best left untreated, and attempts made to heal them so long as the bullet could not be felt lying superficially. Some cases observed recently served to confirm this teaching. It was very difficult to determine from the clinical symptoms the track of the missile with any degree of certainty, as the effects due to direct injury and those at a distance could not well be separated from each other, even when the Röntgen rays in different directions had shown fairly well the situation. Only too easily could more mischief be done by operating than the bullet itself would do. Three very instructive cases were shown in illustration of the view expressed.

At the Medical Society Hr. Schäffer read a paper on ALCOHOL AS A MEANS OF DISINFECTING THE HANDS.

Mechanical means alone did not sufficiently free the hands from germs. The nearest approach to an ideal disinfection was obtained by the use of the method proposed by Ahlfeld, hot water and alcohol. First the hands were to be scrubbed well for at least five minutes in very hot water with a sterile brush and soft soap. This alone, however, would never sterilise the hands. He himself after half-an-hour of such brushing had obtained 120 colonies of germs at the close. The second act was washing for from two to five minutes in alcohol. This would act in three directions. First as a bactericide. It would by no means kill the spores of anthrax, at most the vegetative forms of staphylococci. Secondly, it caused contraction and hardening of the skin. Thirdly, it loosened the fat and epithelium. This important property was however only possessed by concentrated alcohol, not by that which was diluted. It was

necessary, moreover, to wash in several vessels containing alcohol one after the other.

The speaker made a series of disinfection experiments with his own hands, and the nearest to freedom from germs that he could get was from one to five only on inoculating. The nearest approach to the number was obtained by the use of Mikulicz spirit of soap. The usual methods of disinfection by the ordinary antiseptic substances gave results far behind these.

A more important question than the number of germs found after disinfection was their virulence, but we had no means of determining the comparative efficacy of the different methods in regard to this, and we could only proceed on the principle that virulence was in proportion to numbers.

The most trustworthy method of disinfection of the hands was therefore the following: energetic scrubbing of them in hot water with soap for from five to ten minutes, drying with a sterile or at least a clean towel; washing with alcohol for from three to five minutes, and then rinsing in a one-tenth per cent. solution of sublimate.

Hr. Blumberg said the best chemical substance to use after good washing was mercury ethyl diamine, known in commerce as sublimine. It was used in the same concentration as sublimate; it does not make the hands rough.

Hr. Fürbringer thought that some error had crept into these investigations as to disinfection. Beyond all doubt he still believed that washing in alcohol was of the greatest importance in disinfection of hands, and alcohol had certainly a bactericide property. He did not rely upon alcohol alone, but put it in between the scrubbing and washing with the chemical substance.

VIENNA, March 1st, 1902.

DEBATE ON THE PROPHYLAXIS OF TUBERCULOSIS.

CONTINUING the important discussion referred to in my last, Hans Rabl said he could not see what benefits they would derive from Weichselbaum's isolation, &c., in the case of scrofula, which had distinctive characteristics of its own. The organism was one with very low power of resistance, which might take on either a purulent or a genuine tuberculous form. One can, therefore, divide cases of scrofula into two distinct groups; the first is characterised by diseases of the mucous membrane, scrofula eyes, otorrhœa, eczema, enlargement of the glands, thickening of nose, lips, &c.; the second group comprehends changes, such as fungoid growths, ulcerations, abscesses, diseased joints and bones.

Winternitz thought the prophylaxis of tuberculosis would be a sham, even when the bacilli were found. Imagine, he said, all these precautions taken, thereby knowing or acknowledging that the disease is as infectious as has been stated when the bacilli are demonstrated! It is admitted that the sputum may prove infectious when, for instance, a patient or rather a sufferer from the disease is sitting opposite one in a railway train, sputtering the finely-divided mucus about, to be swallowed by the fellow passengers; but that is precisely because the bacilli are not in a spittoon

Again the kidneys and bowels are sources of the disease from which the bacilli may also be transmitted. In his opinion the best prophylaxis is constant attention to maintain the strength of those in good health in order to neutralise the disposition.

LUPUS MILIARIS DISSEMINATUS.

Kreibich brought forward a young girl suffering from lupus miliaris disseminatus on the face. One night it disturbed her sleep from the acute burning and pricking pain that it produced, with great swelling of the face from œdema. Next day the swelling subsided, leaving miliary nodules on the brow, cheeks and chin. Under the microscope each tubercle contained the large lymphoid cell. In thirty-five of these tubercles the "Saurefester" bacilli was present. The infection appears to have been conveyed through the blood, judging from the area so suddenly attacked. In the cervical region there were seen old cicatrices, leaving no doubt as to the existence of previous outbursts in the glands of the tuberculous veins. Kreibich drew a distinction between the large tuberculous cell, and those of lichen pilaris, sarcoma, &c. The large tuberculous cell is certainly more frequently met with and has a finer granular protoplasm with several rounded nuclei, while the "Fremdkörper-riesen zellen" are rarely met with, having little protoplasm and very few nuclei of moderate size. In addition to the tubercle in many parts granulation cells of syphilis and leprosy may be found which may possibly be due to the degenerative influence of the toxines.

Lang thought the "Gelone" prepared plaster which Hr. Bauer used with glycerine was the best prophylactic for lupus that could be devised. It could be sterilised with sublimate or incorporated with any other substance in its application. It was comfortable to the skin, being soft and pliable.

Klein drew attention to the peculiarity of immunity as we knew it by experiment. He found that if he washed the blood corpuscles of an animal with sand quartz and extracted with "isotonic solution of salt" it will not only agglutinate the blood corpuscles of other animals of the same order but it will also agglutinate the blood corpuscles of the same animal from which the blood corpuscles were obtained. Such agglutinated corpuscles are not hæmolytised by the pancreatic extract. From this we may conclude that inactive serum contains active blood corpuscle extracts. This may account for the results obtained in animals with inactive serum when tested, the immunity residing in the corpuscle of that animal and not in the serum.

Benedikt said the ineffectiveness of tuberculosis has been acknowledged since the days of Galen, and did not need to be so laboriously tested in this remote age when people are brought together. Galen asserted that he had seen the husband frequently attacked after the wife had died from tuberculosis and *vice versa*; yet they must all admit, as Skoda and Oppolzer had demonstrated long ago, that the infection is not so easily transmitted as it is generally believed, a fact which had given rise to the conviction in some minds that it could not be directly transmitted. The best cultivating medium was to be found in many of the homes of the people, which were dirty, small, and without ventilation or sunlight. Even many of our so-called "curorts" (hydropathics) are little better than cultivation areas,

where insufficient cleansing, small rooms, and no disinfection was ever practised in regard to either clothing or rooms. There is yet another centre of infection to be found in hospitals and lunatic asylums, where innocent creatures were confined without the slightest precaution. Waiting rooms, barracks, casemates, prisons, &c., are usually accused of having the highest death-rate from tuberculosis, a reproof which was not undeserved. Injuries seem to be very accessible points for the admission of the germ, the vehicle being the sputum, although Galen did not absolve perspiration from them. The collection of the sputum in a conical glass with a disinfecting fluid was a good precaution, but the foundation of all was washing the clothes well and disinfecting with hot air.

The Operating Theatres.

CENTRAL LONDON THROAT AND EAR HOSPITAL.

COMPLETE RADICAL MASTOID OPERATION (STACKE).—Dr. PERCY JAKINS operated on a lad, *et. 12*, who had been admitted for a suppurative discharge from the left ear, which commenced two years ago, preceded by severe pain which lasted twenty-four hours and then the abscess burst. The parents did not then have any special advice. Twelve months later the mother noticed a swelling behind the left ear; she took the patient to a medical man who made an incision into the swelling and let out a little pus. In a week's time the wound had healed up, but the discharge from the external meatus still continued. Twelve months afterwards the child was brought to the hospital. On examination there was found perforation in the upper and posterior segment of the left membrana tympani; bare bone could be felt with a probe, also cholesteatomatous material was seen. The lad had at the same time enlarged tonsils and adenoids which Dr. Jakins decided to remove at once. Fourteen days later the lad came back to the hospital complaining of pain over the left mastoid, and a swelling which was at once incised, and the patient admitted into the hospital. Two days after admission under chloroform a semi-circular incision was made behind the mastoid, the periosteum reflected, the cartilaginous part of the meatus turned out of the osseous and slit into two, the upper flap being removed; with chisel and burr the antrum was next exposed, and a large sequestrum of bone removed; it was found that the cavity was filled with a cholesteatoma; the posterior wall of the osseous meatus was divided, and then the bone covering the facial nerve was found carious. This was gently curetted. It was now apparent that the disease had extended down to the apex of the mastoid; therefore the mastoid cells were all removed. The disease had also involved the attic, and this was well curetted, and all overhanging bone taken away. The large bony cavity was filled with iodoform paste (iodoform suspended in *lotio. acidi. carbolic.* 1-20); the upper part of the wound was stitched up, the lower part being plugged with double cyanide gauze, and the meatal canal kept patent by a large sized drainage-tube. Dr. Jakins said that he had no doubt that the primary cause of the patient's trouble arose from inflammatory or septic material spreading along the Eustachian tube

and so causing acute otitis interna, without doubt due to the adenoids and enlarged tonsils. He thought that if the enlarged tonsils had been removed immediately after the attack of acute otitis then the radical operation he had done need not have been performed. With regard to the operation itself, he pointed out that the complete radical mastoid operation consisted in laying open the antrum, knocking away the posterior wall of the osseous meatus, and cutting a flap in the cartilaginous part of the meatus, thus converting a bottle-shaped bony cavity into a trough. The object of the cartilaginous flap, he explained, was to give more room for inspection and cleanliness. There is, he said, an operation which he used to perform which consisted in exposing the antrum, clearing out all *débris*, and allowing the wound to heal from the back; this is called Schwartz's; but should inflammatory mischief occur again after this operation, there is no outlet for the pent up pus, and serious trouble can arise (as shown in the case published in "Operating Theatres," Jan. 1st, 1902, Cerebellar abscess following chronic discharge from the ear); on the other hand, in the operation just performed (Stacke's) a full outlet remains, so that should any discharge arise, it can be easily treated through the external meatus. The prognosis in these cases, he thought, was extremely good, the mortality is nil; as regards the deafness, in the majority of cases it improves. The only anxiety to the surgeon is when the facial nerve has been irritated during the operation, then facial paralysis supervenes, which lasts from three to nine months.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page, £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 5, 1902.

THE MIDWIVES' BILL.

ONE of the most important measures of recent years, so far as the medical profession is concerned, last week occupied the attention of Parliament. The Midwives' Registration Bill was originally brought forward by a body of laymen with the purpose of rendering compulsory the training and registering of all women practising midwifery. That proposal did not commend itself to the medical profession

as a whole, nor after mature consideration was it endorsed with the approval of the General Medical Council. Speaking broadly, the gist of the proposed measure lay in the recognition by the State of a new order of midwives, entitled by a registrable license to practise obstetrics for gain, and that without direct medical control. In the Bill that fell through in the House of Commons in February, 1900, the two fatal points appear to have been, first, the compulsory nature of the registration, and secondly, the fact that it was left entirely to the judgment of the individual midwife to determine whether a labour was "natural" enough not to demand the calling in of a medical man. The view taken generally by the profession was that a new branch of unqualified practice would be deliberately and unnecessarily called into being by the passage of the Bill, for there was no guarantee that the licensed midwife would not assume duties that fall properly to the medical man to discharge. The general feeling of the profession with regard to the Bill of 1900 may be judged from the fact that out of 6,300 practitioners who responded to a request from the *Lancet* for an expression of their opinion, 4,000 declared their hostility to the proposed legislation, while on the other hand it was regarded favourably by 1,311 only. In the Parliamentary debate of 1900 the definition of a midwife was laid down as "a woman who undertakes for reward to attend women in childbirth where no registered medical practitioner is employed." At the same time an amendment to call such women "midwifery nurses" was rejected, and thereby confirmed the view that the creation of an inferior kind of medical practitioner was in contemplation. The right of the Obstetrical Society to certify the new order was established. Fortunately this projected measure did not become law. Last week the second reading of a new Midwives' Bill was moved by Lord Cecil Manners. It differed from the previous measure in the all-important fact of the omission of the penal clause of 1900. The present Bill, therefore, does not exclude existing incompetent midwives, and in that way clearly defeats the object of its promoters. It resembles a warship without guns. To place a kind of hall-mark upon good midwives is not to prevent the dangers arising from ignorant and drunken women who choose to call themselves midwives. A partial step of that kind does not represent the kind of legislation required to remedy an admitted evil, and merits the opposition which it has met from the General Medical Council and from something like 95 per cent. of the medical profession. The present Government deliberately rejected the united voice of the profession when they threw out the principle of compulsory vaccination. Do they propose once again to run counter to the judgment of the majority of medical practitioners and to their governing body? If so there is likely to be sown a crop of dragons' teeth that will one day exact a reckoning as armed enemies. The second reading of the pre-

sent Bill was secured by the tact of Mr. Ritchie, who urged that all were agreed on the common ground that the poor should be protected against ignorant midwives; but the opposition came from those who urged that more inquiry was needed in order to produce a more drastic measure. To pass a Bill which would be so drastic as to prevent the poor from availing themselves of the assistance of midwives in time of need would be, he remarked, a most unfortunate piece of legislation. Mainly owing to his diplomacy the Bill escaped the peril of being referred to a Select Committee, a procedure which would have infallibly prevented any chance of its being passed, at any rate during the present Session. By a compromise it was referred to the Standing Committee on Law. As matters stand there is every prospect that the Midwives' Bill, in its present permissive form, will shortly become law. It is not at all likely, however, that the promoters of the Bill will be satisfied with their partial success. It will be well, therefore, for the medical profession to maintain a careful hold of the question, and to keep the matter before the attention of the General Medical Council and of the British Medical Association. Even now, every effort should be made to amend the proposed constitution of the Central Midwives' Board, which Lord Manners proposes to constitute as follows:—Four registered medical practitioners; two persons (one of them a woman) to be appointed for three years by the Lord President of the Council, and one person appointed for the same term by the Association of County Councils. A more ridiculous constitution could hardly be imagined for a body entrusted with the responsible task of drawing up rules and regulations and granting certificates. The formation of the controlling board and the framing of rules should beyond a doubt be vested in the General Medical Council and not in the Privy Council.

THE TEACHING OF OBSTETRICS IN ENGLAND.

FOR some reason or other the teaching of practical obstetrics in England has always left much to be desired. While in Continental schools the *manœuvres obstétricales*, or practical training classes, have always been held in high esteem, and attendance thereat duly enforced, here this all-important part of the training is greatly neglected. One naturally wonders where the English student is expected to acquire the *tactus eruditus*, and how he is to learn to recognise the presentations. The only part of the obstetrical curriculum which is carried out in full is that of systematic lectures, which, however useful as a basis for practical work, is of itself of little service in the direction of preparing the student for the actual work of his profession. The weakest part of the system, however, is the very department to which one would look to educate the student, viz., the clinical part. The universal custom in our medical schools is to send the student to attend outside maternity cases, which he does in a more or less

perfunctory manner, for the most part without any assistance beyond his own intelligence and a total lack of experience. It is not that there is any scarcity of lying-in institutions, but these have never been methodically resorted to by students, possibly from a dislike to pay extra fees for something which is not compulsory. What a startling contrast this haphazard system, if system it can be called, presents with the well-ordered and comprehensive instruction imparted at such an institution, for instance, as the Clinique Baudelocque, at Paris. There students are thoroughly grounded in the ordinary everyday work of the lying-in room, they are admitted to assist at the operations and manipulations rendered necessary by pelvic and other abnormalities, and they are carefully instructed in the importance of asepsis and in the invaluable art of diagnosing fetal positions by means of abdominal palpation. Just as medicine and surgery can only be effectually acquired at the bedside, so the art of obstetrics can only be mastered in the lying-in room. The septic terrors of an age long since past brought about the abolition of maternity wards in our general hospitals, and no serious attempt has ever been made to remedy the lapsus thus created. From time to time a feeble and isolated voice has been raised in favour of re-establishing the indoor maternity departments, but so far have found no echo, and so students are left to go on in the same old unsatisfactory way to work out their own salvation, when they get the chance, in private practice. All attempts to improve matters by insisting on more adequate practical teaching of the subject have fallen to the ground simply because the General Medical Council has felt that, under existing circumstances, it would be idle to insist upon the impossible. But reform is impossible only because those who could initiate it are oblivious of, or indifferent to, the urgent necessity therefor. We are confronted with the possibility that if midwives are adequately trained they may, in some instances, know more than the medical attendant, should the latter be a young man fresh from the schools. If hospital managers will not rehabilitate the maternity wards arrangements should be made whereby the ample store of material available in our lying-in institutions and infirmaries should be made available for purposes of the methodical instruction of students. Until that is done the English school of obstetrics will remain a by-word among nations.

THE GOVERNMENT AND LONDON WATER SUPPLY.

THE history of the water supply of the metropolis records a prolonged conflict between public and private interests in the richest and greatest city of the world. In the United Kingdom there are no less than 918 public bodies that manage local water supplies, and of that number 913 are directly elected municipal authorities. Some of these concerns, as at Liverpool, Manchester, and Birmingham, are carried on with great profit and saving to the citizens

who have acquired the control of the monopoly in question. Curiously enough, London is not permitted to manage its own affairs in the business-like way that is open to every petty town and district in the kingdom. Imperial Parliament asserts a right to dictate the way in which certain parts of administrative London shall be ruled. The police of Greater London, for instance, are not under the control of the citizens, but of the Home Secretary. The Metropolitan Asylums Board, again, is not an electoral body representative of the citizens, but its members are nominated by Government and by various local bodies. Of recent years the London County Council has sprung into vigorous being, and has been permitted to assume a central control of a few matters of common municipal interest. Naturally the Council, as a progressive body, desired to secure the advantages of a water supply owned by the public instead of by a number of private corporations. It has been proved again and again that the water companies have failed both in the matter of quantity and of quality, to say nothing of pressure, constancy of supply, and depth of pipes. The County Council has fought the water battle of London year after year, and has so far been able to enforce the partial acceptance of its views as to purchase and to control upon an unwilling Government. The present Bill introduced by Mr. Balfour's Ministry provides financial terms for the water companies that may be regarded as extravagant. The more important matter, however, is that it practically takes the control of the water supply out of the hands of the County Council and places it in those of an unwieldy non-elective body of sixty-nine members. Nothing of the kind is required in other towns, where a small committee of ten or fifteen members is found to answer all purposes. It is apparently only when London is concerned that the necessity of creating such unwieldy bodies suggests itself to the Government. The Metropolitan Asylums Board is a non-elective body of that kind, and, although its work is undoubtedly good, yet the lavishness of its expenditure makes it desirable that the Board should be brought under the direct electoral control of the ratepayers. The defunct Metropolitan Board of Works, a corrupt and inefficient body now happily replaced by the County Council, presented another glaring instance of the danger of vesting important administrative duties in the hands of a non-electoral executive. Yet with all these and other object lessons in view the Government has obstinately maintained the resolution to entrust the control of London water to a non-representative Board. The chaotic band to be created under the scheme of the Government Bill is to consist of sixty-nine members to be nominated by the Borough Councils and by the various authorities outside administrative London. The County Council, which knows all about the water question, and is a great impartial and central representative governing body, is to be represented on this fatuous new Board by ten representatives. It is impossible to avoid the conclusion that such a proposal covers a

thinly disguised attack on the County Council. The Water Board, if Parliament be weak enough to carry the Government proposals into effect, will be virtually absolute in power, inasmuch as it will be outside the electoral control of the ratepayers. If established it will be a law unto itself and there will be nothing to prevent its rapid degeneration into a second Metropolitan Board of Works. Sooner or later corruption and dissolution have overtaken every administrative body having command of immense revenues if that body be independent of direct public control. The curious irony of the situation becomes apparent when it is remembered that at the last election, the County Council was returned by a large majority with a popular mandate to purchase and to acquire control of the water companies. Conservative London Members of Parliament who support the Government Bill are therefore opposing the deliberately expressed wish of their electorates. There is another point worth noting. In placing obstacles in the way of the popular control of water, Mr. Balfour's Ministry is once more running dead against the opinion of the medical profession, as unanimously declared in the leading medical journals. Mr. Balfour flouted the profession in the matter of vaccination, he has repeatedly tried to do so on the midwives' question, and apparently he invites their hostility upon the principle of the present London Water Bill. Those interested in the sanitary well-being of other parts of the United Kingdom where the water supply is not under municipal control will do well to mark, learn, and inwardly digest the lessons to be gathered from the vicissitudes of the water supply in the metropolis.

Notes on Current Topics.

The General Medical Council.

HAVING formally taken cognizance of the situation as between itself and the Royal Colleges of London, in respect of the recognition of institutions for the teaching of preliminary scientific subjects, the Council held its hand and virtually withdrew its threat to report adversely to the Privy Council. It may be conceded that in view of the lack of unanimity on the matter in the Council itself, it probably did wisely in not proceeding to extremities. The only real matter for surprise and disappointment is that this attitude did not earlier commend itself for adoption. We repudiate any sympathy with the Royal Colleges in what we are fain to consider their ill-advised and unpatriotic, however legal, action in thwarting the Council's attempts to co-ordinate and level up the standard of scientific education, but it was hardly worth while to enter upon a struggle which has finished so ingloriously. Our only consolation lies in the hope that the Royal Colleges, after a period of not unnatural exultation, will make such concessions as experience may prove to be necessary in order to preserve to the Council that preponderating control over the whole medical curriculum which has done so much to elevate medical

education in the past, and holds out such promise for the future. The one point which we regard as essential and fundamental is that there shall be no tampering with the integrity of the five years' curriculum, and it is sincerely to be hoped that a *modus vivendi* will be elaborated which, without sacrificing the privileges to which the English Conjoint Board attaches so much importance, will secure five years for medical study proper.

The Dinner of the Royal Medical and Chirurgical Society.

THE Fellows of the Royal Medical and Chirurgical Society met at dinner on Wednesday of last week in the Whitehall Rooms of the Hotel Metropole, Dr. C. Theodore Williams occupying the chair in the absence of the President, Dr. F. W. Pavy, owing to domestic bereavement. Some 120 Fellows with their guests were present, among them being Sir Walter Sendall, G.C.M.G., Sir Wm. Turner, Sir Dyce Duckworth, Sir Thomas Smith, Mr. A. Willett (President-elect), Mr. Watson Cheyne, Mr. Howard Marsh, Dr. Peter Horrocks, and Dr. Urban Pritchard; Sir Thomas Barlow, Bart., and Mr. Clinton Dent (hon. secretaries); Mr. Howse, President of the Royal College of Surgeons; Mr. W. W. Oules, R.A., Dr. Conan Doyle, &c., &c. The Chairman read a telegram from the President regretting his enforced absence, which received a sympathetic reception. After the toasts of his Majesty (the Patron of the Society) and her Majesty the Queen, the Prince and Princess of Wales, and the other members of the Royal family, the Chairman proposed the toast of "The Royal Medical and Chirurgical Society," into the history and progress of which he entered at considerable length, showing that it is a flourishing and progressive institution occupying a foremost position in the British medical world. The toast of "Our Guests," proposed by Mr. Alfred Willett, was responded to by Sir Walter Sendall and Dr. Conan Doyle. The latter laid claim to a feeling of embarrassment, of which he gave no outward and visible manifestation, on the ground that he felt like a deserter dining with his old regiment, or, at best, like a full private dining at his officers' mess. Although he no longer practised his profession, he fully appreciated the value to the individual of a medical education, which, he urged, was the truest basis for thought and the truest basis for life, because it went down to its very roots. He insisted on the beneficent influence of "the parish priests of science," the humble general practitioner, whose inconspicuous life was to him a continual inspiration, characterised as it was by a high sense of duty which reached through life to death. Dr. George Ogilvie, in response to a general call, made some delightfully humorous remarks in which he traced the steps of Scottish migration south of the Tweed from prehistoric times, embodying therein some anecdotes which considerations of space unfortunately prevent our reproducing. The proceedings concluded with a vote of thanks to the Chairman, and a very pleasant evening was then brought to a close.

Chloroform Mortality in France.

AN instructive debate on the incidence and prevention of death from chloroform and other anæsthetics has occupied several recent meetings of the French Academy of Sciences. The subject does not seem to be one in which anything approaching absolute precision can be arrived at, probably because the personal equation plays too preponderating a part in the innocuousness or otherwise of the induction of anæsthesia. Nevertheless, the prevailing opinion among French surgeons appears to be that when carefully administered chloroform is not attended by greater risk to life than the other anæsthetics in general use, not even in respect of the subjects of organic heart disease. Unfortunately we are no nearer a solution of the problem which is the best, i.e., the proper, way to administer the drug. Inhalers of any kind seem to be unknown across the Channel, yet so long as chloroform is poured on to a mask or towel error of judgment and carelessness are certain to cause a certain proportion of fatalities. In the course of the debate it was confidently asserted that there are more accidents from chloroform in Great Britain than in any other country, although it cannot be said that the methods in vogue in the two countries present any great points of difference. In estimating the value of a comparison of this kind, it is obvious that the absolute mortality must be compared with the number of administrations, and these figures, as it happens, are available neither there nor here. We see no way of obtaining this very necessary information short of a system of compulsory notification of chloroform administration, an innovation which has not as yet cast its shadow over the medical horizon.

"Off" Licences and the Government.

THE present Government has been often enough reproached for its want of courage and enterprise in attacking the difficult subject of temperance legislation. Now that they have brought forward a licensing measure they are not altogether to be congratulated on their performance. Clause 8 of that Bill interferes directly with the sale of liquor in grocers' shops, or "off" licences. The brewing interest in Parliament is enormous, and in the present instance has most likely been brought to bear against the retail sale of liquor in places other than in public-houses. That may possibly explain the true inwardness of the matter, or it may be simply a further illustration of Mr. Balfour's *dilettante* method of handling certain phases of social life, such as that which gave birth to the "conscientious objector," and is now pushing the Midwives Bill through Parliament in the teeth of the General Medical Council and the vast majority of the medical profession. Why should grocers' licences be abolished? Is not the unnecessary consumption of drink likely to be lessened if beer, wine, and spirits be procured at a grocer's shop instead of a public-house? After three years' patient investigation the majority report of the Royal Commis-

sion of 1896 saw no reason to advise any alteration of the present system as regards the combination of the trades of grocer and wine and spirit seller. "Off" license holders are liable to exactly the same police regulations as holders of ordinary licences. It is hard to imagine any reasonable defence of the Government proposal to abolish "off" licences. The pith of Clause 8 lies in giving justices absolute control of "off" licenses. That principle has failed in the case of "off" beer licences, for under justices' control the number of tied houses has greatly increased. The result of Mr. Ritchie's proposal must infallibly be to create a monopoly in the "off" trade such as now exists in the "on" trade. From almost every conceivable point of view the proposed extension in the Government Bill is as unnecessary as it is unjust and unwise.

The War against the Ship Rat.

THE discovery of the part played by the ship rat in the carrying of plague from port to port has resulted in a war of extermination on the part of all progressive port sanitary authorities. In the Port of London the rats have been destroyed literally by tens of thousands. From a recently-issued report we gather that between November 24th and December 31st six cases of plague and thirteen cases of enteric fever were dealt with, and during that period 10,164 rats were destroyed. The Medical Officer of Health, Dr. Williams, in a further report for January, states that 2,293 ships were inspected, and 7,626 rats destroyed. The total number of rats accounted for since the commencement of the raid has amounted to considerably over 100,000. In one large steamer, which was disinfected on account of small-pox, no fewer than 1,000 dead rats were found after the process of fumigation. This satisfactory record should have a distinctly stimulating value to other port authorities throughout the United Kingdom, inasmuch as all of them are exposed sooner or later to the risk of invasion by plague. Concerted action, indeed, lies at the root of success in warding off this special danger. Clearly, it is little use killing off the rats on board the ships in London ports if they are allowed to pass unscathed, say at Southampton, Cardiff, Aberdeen, or Belfast. It would be worth careful consideration whether the responsibility of keeping ships free from rats could not be fastened upon shipowners.

A "PEOPLES' Medical Defence Union" has been formed at Birkenhead, apparently with the object of defending the practice of medicine by one Pleavin, who claims to be M.D. (U.S.A.), whatever that may be. Mr. Pleavin addressed the meeting, and spoke strongly on the conduct of the Registrar in refusing his certificate of death, winding up with a resolution calling upon the borough members of Parliament to ask the Registrar-General for an explanation of his conduct in directing the refusal of such certificates, and censuring the borough coroner. This, on the part of an American quack, really borders on impertinence.

Small-pox in London.

UNHAPPILY there is no change in the stereotyped report of the increase of the small-pox outbreak in London. The authorities have shown a praiseworthy energy and thoroughness in grappling with the disease, and it may be safely said that no similar epidemic has been hitherto handled with a better preventive organisation. The Metropolitan Asylums Board have so far kept pace with the demand for hospital accommodation, and have provided the most efficient ambulance system that the world has ever known. Chicken-pox has been rendered compulsorily notifiable in the metropolitan area, and an insidious risk has been thereby averted. Last week the London County Council adopted another most important step towards staying infection. Small-pox has been so long practically absent from London that many medical practitioners are not familiar with its objective appearances. Moreover the disease is so varied in its manifestations and so often modified as the result of vaccination that its existence can be recognised only by those who have had considerable experience of the malady. Lastly, it happens not infrequently that patients are often unable to pay the fees of consultants. All these difficulties have been met by the wise action of the Council, who have appointed a number of medical men in various parts of London who may be consulted free of charge in all doubtful cases. This arrangement is to continue in force so long as chicken-pox remains a notifiable disease or until further notice. This activity on the part of the metropolitan local authorities is of direct importance to every town throughout the United Kingdom, inasmuch as it has repeatedly happened during the present epidemic that the disease has been conveyed from London to distant parts of the country. The actual returns since our last issue have been as follows: On Tuesday, February 25th, 47 fresh cases, with 1,320 persons under treatment; on Wednesday 38 fresh cases; on Thursday, 44; on Friday, 45, and 1,350 cases under treatment; on Sunday, 99 fresh cases, and on Monday, 78. The deaths from small-pox in London last week amounted to 64, as against 39, 64 and 54 in the preceding three weeks.

The Cork Crab Case.

OUR readers will doubtless remember a peculiar case known as the Cork crab case, in which illness had resulted from eating crabs which were unfitted for human food, and to which we alluded in an article on ptomaine poisoning. The case from a legal point of view is one of considerable interest. The unfortunate person who ate the crabs was awarded damages by a divisional court. This decision was subsequently confirmed by the King's Bench Division, and has been reaffirmed by the Court of Appeal. Apparently, the crabs were sold as human food, and the Lord Chancellor, in giving judgment, held that the question to be decided was governed by the Sale of Goods Act, and that the

transaction in this case was of such a nature that there was an implied warranty. This is a most important decision, and one which affects thousands of persons. Milk-sellers will be intimately concerned, as the decision will obviously affect the lax manner in which unsound milk is sold. Indeed, in this respect, if the public only grasp its full significance, the consequences for sellers of milk will be unpleasant, though by no means undeserved. It seems to us that the employment known as baby-farming can now be profitably diversified by an employment of exacting compensation from the milkman because he supplied the unsound milk which caused the illness or death of the infant.

Quackery in Silk and Velvet.

IN the present year of grace the unqualified medical practitioner is carrying on operations on a scale probably never hitherto reached in the United Kingdom. In and around Bond Street, for instance, one of the wealthiest quarters of the Metropolis, a score or more electricians, bone-setters, masseurs, skin, electrolysis, and hair experts, live and flourish like green bay trees. Some of them draw revenues that would compare favourably with ninety-nine out of a hundred specialists in Harley Street. Their operations are carried on in a strictly commercial manner, and public advertisement is the sheet anchor of the whole affair. The fees charged vary from half-a-guinea to one or two guineas and sometimes more for a visit. Some of these unlicensed practitioners are in the habit of attending patients systematically at their own homes. This form of competition clearly affects the qualified consultants and specialists, who are thus deprived of many thousands of pounds every year. Hitherto the field of quackery has been for the most part restricted to the poorer classes, whereby the income of the general practitioner has been most seriously diminished. It is to be hoped that the medical profession will one day insist on a proper protection of their own interests and at the same time of those of the community at large. If the General Medical Council cannot bring pressure to bear upon Parliament, then it will be well to demand a radical change in the constitution of that body, so that it may be converted into a representative governing body with real power to protect the profession from which its revenues are drawn.

The Soldier's Heart and his Knapsack.

THE fact that prolonged military service has, generally speaking, an unfavourable effect upon the heart and vascular system has long been recognised. Soldiers are especially liable to aneurysm, and a large number are invalided annually in our own army on account of heart troubles. The cause appears to be not remotely connected with the continuous and prolonged physical exertion that are demanded by an unscientific military administration. Everyone knows that a horse breaks down rapidly if worked to the utmost limit without intervals of

rest, whereas with a day off, say, twice a week, the same animal would last comfortably for a reasonable term of years. Some recent experiments conducted by Professor Zuntz, of Berlin, and Dr. Schumberg, of Hanover, appear to point to the existence of much the same principle as regards soldiers. Five army medical cadets were marched a stated distance under varying conditions of food and amount of weight carried, while the physiological results on the circulatory, excretory, nervous and other systems of the body were carefully noted. The character of the food was found to be important, and on ordinary rations it was found necessary that one day of rest should follow three of heavy marching, in order to enable the body to restore the fat used up in the production of energy. The men lost weight, that is to say, they lost their fat. The sphygmograph showed that with an excessive load the action of the heart increased to one hundred and forty or fifty beats per minute. This result was attributed to fatigue of the cardiac muscle, and the investigators concluded that sixty-eight pounds is the heaviest weight that can be carried without risk of permanent damage to the heart. All this is of first-rate importance to sound army administration.

Bacteriological Prophecy in Comedy.

It is frequently said that the existence of pathogenic microbes had long been foreseen by the eye of imagination ere the bacteriologist was abroad. It has been discovered that the disease-bearing bacterium was foreshadowed by Samuel Foote in his comedy, "The Devil on Two Sticks," written in 1768. In it the President of the College of Physicians lectures:—"Brethren and Students,—I am going to open to you some notable discoveries that I have made respecting the source or primary cause of all distempers incidental to the human machine, and these, brethren, I attribute to certain animalculæ or piscatory entities, that insinuate themselves through the pores into the blood, and in that fluid sport, toss and tumble about like mackerel or cod-fish in the great deep; and to convince you that this is not a mere *gratis dictum*, an hypothesis only, I will give you demonstrative proof. Bring hither the microscope!" &c.

The Administration of Morphine.

The action for damages brought against a medical man by a nurse, consequent on the alleged continuous and unjustifiable administration of morphia, which entertained public curiosity during last week, directs attention to the grave responsibility resting upon every practitioner who advises the medicinal use of morphia, cocaine, and like bodies capable of initiating a morbid habit. It is well that this matter should be faced. It is often said that habits of alcoholism have been entered upon under "medical orders," and although such is undoubtedly in many instances but a manifestation of the palliative mendacity characteristic of the confirmed inebriate, it is to be feared that a careless and unscientific acquiescence on the part of the medical practitioner in sanctioning a

self-administration of alcohol has in only too many cases led to the most disastrous results. The same holds good of morphia and cocaine. Dr. Oscar Jennings, of Paris, in the recent edition of his well-known little work on the subject ("On the Cure of the Morphia Habit," 1901), admirably portrays the clinical features of the morphia *habitués* and shows the difficulties in the way of their adequate management. In these days, when narcotic drugs can be obtained without difficulty, and when even the method of hypodermic administration is daily demonstrated on the stage of one of London's most famous theatres, it is well that every medical man should studiously guard himself against the risk of being made responsible for the initiation of a habit which makes for moral decadence and inevitably leads to physical degeneration. Under these circumstances surely a word to the wise is likely to be enough!

The Therapeutic Influence of Scenery.

THE medical man in his study of climatology is rather apt to limit his mental vision. In the selection of a suitable health station for his patient he oftentimes directs his whole attention to the physical characters of the place, and forgets to consider the probable influence of the natural features of the district on the mind of the invalid. The action of psychological impressions is not infrequently of quite as great importance as any alteration of physiological processes. Indeed, it must not be forgotten that much of the advantage of "a change" often arises from the readjustment of the psychical life of the patient, as well as the rectification of physical conditions. The wise physician cannot afford to neglect this matter, and as an aid to a wider outlook we venture to recommend a careful study of Lord Avebury's charming new work, "The Scenery of England and the Causes to which it is due."

The Aerial Dissemination of Small-pox.

DR. J. C. THRESH, the able Medical Officer of Health for Essex, has recently drawn attention to the spread of variola by means of the wind. This is no new doctrine, but Dr. Thresh's evidence is very convincing that we are acting in opposition to well-substantiated fact, that in short our methods of isolation are imperfect and dangerous. It has been amply demonstrated that the hospital ships moored in the Thames are a serious source of danger to communities in the near neighbourhood. The number of cases in the Orsett Union, that nearest the ships, represent a rate of 8.6 per 1,000, while for the rest of Essex it is only 0.21 per 1,000 of the population. Dr. Thresh shows that if London had been affected in the proportion in which the Essex division under notice has suffered, no less than 500,000 cases would have occurred within the last seven months. The virus of variola still remains unknown, but whether it proves to be a bacillus or member of the bacteria group, or is ultimately shown to depend on some protozoal organism, as some suggest, there can be no doubt

that its infectivity is dependent on characters which are capable of allowing action over wide areas. In some respects it is not unlike typhus. We have learnt the danger of aggregating such cases, but at least in practice the same truth is not recognised in connection with variola. Dr. Thresh's observations seem to show that variolous infection may be wind-borne for a distance of from two to three miles. It is to be hoped that the medical officers of the Local Government Board will look into this matter at once, and that some authoritative statement will be speedily forthcoming.

Mastitis in Typhoid Fever.

It may truly be said that the more gradual the onset of any disease the greater is, as a rule, the difficulty in making a positive diagnosis, and the greater the number of complications which have been found associated with it the more embarrassing will the prognosis be. In the last few years the number of what may be termed recognised and legitimate complications of typhoid fever has been largely added to. The most recent addition is perhaps that of mastitis, an addition which is apparently justifiable. The number of cases recorded, and the care with which fallacies have been excluded in many of them, prove that the association of the conditions was not merely accidental. According to Dr. Thomas McCrae (a) mastitis as a complication of typhoid fever is not confined to females or necessarily associated with a functioning gland, and usually occurs late in the attack. Both breasts are involved in about 50 per cent. of the cases, and suppuration occurs in about the same number. The occurrence of mastitis is not apparently of any special moment in the prognosis of typhoid.

Recent Views on Prostatectomy.

It is satisfactory to observe signs that the somewhat acute discussion on the subject of the operative treatment of senile hypertrophy of the prostate is showing indication of becoming less heated and more rational. Many, who followed the course of the discussion, felt that the principal questions at issue were based on pathological and anatomical grounds, rather than surgical. Two points were brought prominently, if somewhat indirectly, forward. The first was the necessity of clearly defining what was meant by the "capsule" of the prostate. Some understand by this term the fascial covering derived from the pelvic fascia inside which lie the prostatic plexus of veins which separates the gland from its capsule; others regard the fibrous envelope, which, in normal cases is intimately attached to the structure of the gland and outside which the plexus lies, as the "capsule." The second point which underlay many of the difficulties in the discussion was the somewhat general failure to differentiate between the uniformly enlarged prostate met with in old men and the prostate, which is the

site of multiple fibro-adenomatous tumours. Mr. Hurry Fenwick, in a recent article (a) clears up these points and many others associated with them. He points out that though in the adult, or in the "tough" prostate, the gland and its capsule (inner or true) are densely adherent, yet in the old adenomatous prostate the tumours have displaced the tissue of the gland, so that it lies in fine lines near the capsule. There is, however, a certain amount of difficulty in following Mr. Fenwick when he says that the "ripeness" for removal can be judged by the "tension of the capsule." Though it is scarcely desirable to seek to open up again the wordy warfare, we cannot pass over Mr. Fenwick's reference to it without observing that had his colleague stated his case as Mr. Fenwick has done no discussion would have arisen. It is one thing to speak of complete enucleation of the prostate and quite another to speak of the complete enucleation of adenomatous masses without any direct attempt being made to remove what remains of the gland adherent to its capsule.

A New Method for Preventing the Deposit of Moisture on Laryngeal Mirrors.

THE difficulty of preventing the deposit of moisture on laryngeal mirrors during a prolonged examination is well known. Heat will, of course, prevent its deposit temporarily, but, in some cases, as where electric light is used as a source of heat illuminant, it is not always at hand. Consequently, it may be of interest to many medical men to know that there is a reliable alternative. This alternative is to be found in what is known as "le crayon anti-buée," which Dr. Walker Downie has recently drawn attention to as of value for the purpose we mention. The laryngeal mirror is polished with a soft cloth, and then gently rubbed over with the crayon, it can then be breathed upon without impairing its brightness. It is probable that the use of these crayons is already familiar to many who have to constantly wear glasses, as it was, we believe, primarily introduced with the object of preventing the deposit of rain on the latter. From a trial which we recently made of the substance we fancy that it is even more suited for the purpose for which Dr. Downie recommends it than for the purpose for which it is actually intended, inasmuch as, according to our experience, it will effectually prevent the dulling of glass from respiration or such like causes, although an excess of moisture, as occurs in the case of rain beating against glasses, will in a very short time destroy its action. The crayon is also of value for preventing the dulling of the eyepiece of microscopes during use.

THE death is announced of Dr. Thomas Pearce, one of the oldest and best-known practitioners of Plymouth, at the age of 74. The history of the Pearce family as physicians extends back with unbroken continuity through several generations.

(a) *Practitioner*, February.

The Identification of Human Blood.

IN the course of a recent notorious murder trial the medico-legal aspects of human blood identification were brought into prominence. The chain of evidence on which the crime of murder was brought home to the accused man was altogether circumstantial. Human blood was present on the handle of a knife found entangled in the hair of the murdered girl. Similar stains were also found on the clothing of the prisoner, but the most important point was the presence of blood on the floor of the van driven by the accused. Expert evidence was given by a leading medico-legal authority, who stated the age of the bloodstain to have been probably within certain defined limits. Counsel for the defence naturally made the most he could out of the uncertainty of the evidence bearing on the age of the blood stains. He does not appear, however, to have laid much stress upon the all-important point that the blood found on the floor of the cart was human blood. Fortunately it is possible to determine by spectroscopic and other more recent methods with practically absolute certainty whether any given blood stain is or is not of human origin. In the present case the expert witness was able to state with confidence that the blood was of human origin. Any possible shadow of a doubt was fortunately disposed of by other incriminating evidence, which no ingenuity of counsel could explain away. The discovery of blood corpuscles appears to be the only clue to the date of the shedding of the blood, and that must necessarily vary within certain limits according to the conditions of exposure.

Corporal Punishment.

THE advantages and dangers of corporal punishment have been much discussed, but we had thought that it had generally been recognised that to allow teachers to exercise their discretion in the infliction of physical pain for mental incompetence, was both inhuman and dangerous, and indicated a sad lack in the tact and talent for teaching. We are astonished therefore to see it reported that the Hornsey School Board have adopted a resolution conferring power upon assistant teachers to inflict corporal punishment in the Board's school. We do not know if this particular Board have availed themselves of the opportunity of appointing a Medical Adviser, but we think that they should inform their teachers that should they inflict physical damage to their pupils, they render themselves liable to prosecution, when it may be presumed the Board would quickly rescind its resolution.

Influenza at Home and Abroad.

THE microbe of influenza has made its influence felt in Government circles on both sides of the English Channel, and both Legislatures have been greatly hampered by the enforced absence of prominent members. Fortunately, in view of party politics, this particular microbe is no respecter of persons, and smites the just and the unjust—that is to say, both sides of the House—alike, so that the

division lists have not been unduly disturbed. The list of distinguished victims is too long even to glance at, but happily the mortality rate is very low.

Absurd Rumours.

A COPIOUS crop of silly rumours has sprung up all over the country to the effect that persons who had been revaccinated have had to undergo amputation or other serious operation as the result thereof. So circumstantial were some of these rumours that certain firms have found it necessary to publish categorical disclaimers. Absurd as such rumours are, they do an immense amount of mischief among the unthinking and the ignorant, just the people in fact who are but too apt to entertain "strong views" on the value and effects of vaccination.

DR. SEYMOUR GRAVE TOLLER, M.D., M.R.C.P. Lond., late physician to the Kasr-el-Ain Hospital, Cairo, a young physician, who as a student had a most brilliant career, died last week at his residence at Cairo, at the early age of 35.

DR. GEORGE ROBERT S. MACGREGOR, Medical Officer of Health for the Bingley district (Yorkshire) died on Saturday, aged 46 years. He was the son of the Rev. R. MacGregor, of Canisbay, Caithness, and was educated at Aberdeen and Edinburgh.

DR. E. TRAVERS SMITH has been appointed a physician to the Richmond, Whitworth, and Hardwicke Hospitals, to which he was formerly assistant physician.

THE EARL OF ROSEBERRY will preside at the annual meeting of the Royal National Hospital for Consumption and Diseases of the Chest, Ventnor (of which he is President), on March 18th.

LORD SANDHURST has accepted the office of Chairman of the weekly Board of Governors of the Middlesex Hospital, an office which he formerly held before being appointed Governor of Bombay.

MAJOR H. KENDLEY, Medical Officer at Patiala (India), was recently mobbed and severely assaulted by the populace at Patiala in a plague riot. He was rescued by the Imperial Service Troops.

CAPTAIN INKSON, V.C., of the Royal Army Medical Corps, an old student of University College and Hospital, was entertained at dinner last week by the Union Society of the College and Hospital, Professor G. Vivian Poore presiding. Captain Inkson, it will be remembered, won the Victoria Cross at Pieter's Hill, being recommended for distinguished bravery by General Buller.

Scotland.

[FROM OUR OWN CORRESPONDENT.]

THE GLASGOW FACULTY AND THE GENERAL MEDICAL COUNCIL.

A WELL-ATTENDED meeting of the recently-constituted Association of the Licentiatees of the Faculty of Physicians and Surgeons, Glasgow, was held in the Faculty Hall, St. Vincent Street, on Thursday last. The chair, in the unavoidable absence of Prof. H. E. Clark, honorary president, was occupied by Mr. Burges

the president. He said the objects for which they were met together were two-fold. They wished to give the licentiates scattered over the country an opportunity of joining the Association, and they were also met to consider the action of the General Medical Council in connection with its edict regarding the sale of scheduled poisons by general practitioners having open shops. That edict did not compel them to shut their shops, but it practically made it dangerous for them to retain them, and already a number of men had sold their shops and others would gladly do so. They felt their rights, which as a class they had enjoyed from time immemorial, were being interfered with by a body which ought, instead of doing so, to have conserved their interests. An animated discussion followed the Chairman's remarks, and the following resolutions were proposed, seconded, and unanimously carried:—

1. "That a committee be appointed to approach the Faculty of Physicians and Surgeons, Glasgow, to point out that, in our opinion, the recent edict of the General Medical Council is a serious infringement of the rights in pharmacy held by the licentiates under their diploma, and to request them to take steps for their protection."

2. "That the Council be empowered to represent to the General Medical Council, the effect of their recent edict upon the medical practice of the district, and to defend our system of open surgeries."

3. "That the Council be empowered to approach the members of Parliament for Glasgow, and the West of Scotland either independently or in conjunction with other medical societies, with a view to securing a reform of the constitution of the General Medical Council and a modification of its penal powers."

Dr. Lindsay Steven, who was present at the meeting, said he was at one with the licentiates that they had a serious grievance against the Council in regard to this matter. He was glad that they had appointed a committee to approach the Faculty, and he would be glad to do what he could to further their objects. Dr. Barlow also expressed his willingness to support the licentiates in the Faculty. Drs. Steven and Barlow are Fellows of the Faculty appointed by the licentiates to represent them.

INADEQUACY OF DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

At a numerously-attended meeting of the Glasgow and West of Scotland Branch of the British Medical Association on Friday last in the Faculty Hall, a motion was proposed by Dr. J. Stewart, president of the Southern Medical Society, and seconded by Dr. D. Couper, president of the Eastern Medical Society, "That the Council of the Branch be instructed to draw up a memorial for presentation to Parliament calling attention to (1) the inadequacy of the direct representation on the General Medical Council, and (2) the exceptional penal powers possessed by the General Medical Council, and praying for an increase in the number of direct representatives on the Council, and a modification or withdrawal of its penal powers. And, further, that the Branch Council be empowered to solicit the co-operation of the other Scottish branches of the British Medical Association in this matter. It was announced by the Secretary that a letter had been received from the General Secretary stating that the Council of London were drafting a Bill for presentation to Parliament on the subject, and it was ultimately agreed to delay proceeding further meantime on the lines of Dr. Stewart's motion. The Secretary, however, was instructed to invite the co-operation of the other Scotch branches in endeavouring to expedite the introduction of the proposed Bill to Parliament by the Council of the British Medical Association.

THE INDIAN MEDICAL STAFF CORPS AND SCOTCH STUDENTS.

The Edinburgh Medical School has good reason to feel proud of its graduates who represented it in the recent examination for entrance into the Indian Medical Staff Corps. Out of ten Edinburgh candidates six succeeded in gaining places, which reflects creditably on the standard of training received here. Dr. W. C. Ross, a former president of the S.E.C., and editor of the

Student, gained the second place, whilst Dr. F. A. Bernardo, Walker, Rundall, Wilson, Trafford, Manasse, Paton, and Robertson gained places. These gentlemen proceed shortly to Netley for a four months' course of training before leaving for India.

Obituary.

FLEET-SURGEON HENRY BEAUMONT, R.N.

We regret to report the death, from pneumonia and heart failure, on Wednesday, February 12th, 1902, of Fleet-Surgeon Henry Beaumont, R.N., at Idrone Terrace, Blackrock, Co. Dublin. Fleet-Surgeon Beaumont was born in the year 1845. His father was Frederick Augustus Beaumont, who held a good position in the Bank of Ireland up to the date of his death. He resided at Williams Town, Co. Dublin.

Henry Beaumont was educated at Jones' School, Monkstown. He selected medicine as his profession, and studied at the Royal City of Dublin Hospital and the School of the Royal College of Surgeons. He took the License of the Royal College of Surgeons in Ireland in 1866, and the License in Medicine and Midwifery of the Royal College of Physicians in Ireland in 1867. After he was qualified he took up practice for three years at Holyhead, and was then appointed to a dispensary on the Coast of Donegal. Not liking the loneliness of country dispensary work, he gave it up in a very short time, and entered the Royal Navy in 1870, and served in different ships as surgeon in many parts of the world. He retired on pension from the Service in October, 1891, having served for twenty-one years, and went to reside in the neighbourhood of Blackrock, Co. Dublin, where he looked up many of his former fellow-students and lived a quiet bachelor life in the society of his friends and of his pet birds. Although of a rather reserved manner, he was a most charming companion, and the quaint dry humour with which he used to express himself often amused and carried food for reflection to his friends. He was most charitable, and, at the same time, very anxious that nothing should be said about his charities. Latterly, he became a member of the Committee of the National Children's Hospital in Harcourt Street, and also joined the Committee of the Dublin Red-Cross Nursing Sisters' Home, in both of which institutions he took the warmest interest, and hardly ever missed a meeting of their boards.

He was a clear-headed business man, possessing at the same time the most kind and thoughtful disposition, and all through his long and painful illness, of which he was most conscious, though he bore it with apparent stoic indifference, he preserved the same courageous front. When he was told of the serious danger he was in, two days before his death, by a medical friend, his reply was characteristic. He said: "He had to face the music and there was no use shirking it," and that he must "meet calmly whatever came."

His funeral took place at Mount Jerome, and was attended by his uncle, Captain Beaumont, his two cousins, and a few dear and faithful friends whom he had loved and respected and who had been with him to the end.

DR. S. A. K. STRAHAN.

THROUGHOUT all medico-literary circles the death of this distinguished psychologist will be mourned. Few men ever threw themselves more wholly into their studies than the subject of this memoir, and few writers have ever attained such a lucidity in writing on mental pathology. His clinical pictures of insanity equalled those of Clouston, and his charm of writing was as fascinating as that of Maudeesley.

He contributed many papers to the *Journal of Mental Science*, and his book, "Suicide and Insanity," was at once recognised as an authority both by the medical and legal profession. For some years he was medical superintendent of the Northampton County Asylum, Berrywood, but hoping to benefit his health, which latterly had not been good, Dr. Strahan relinquished this appointment, and some months ago went to South Africa, where he, unfortunately, contracted malarial

fever, which necessitated his return to England, and he died somewhat suddenly last week in London. He possessed the degrees of M.D., M.Ch., E.U.I., and B.S.

DR. PAUL F. MUNDE, OF NEW YORK.

We regret to have to chronicle the death of the well-known American gynecologist. Dr. P. F. Mundé, who died recently at New York. Dr. Mundé was perhaps best known in connection with an excellent work on the "Diseases of Women," which he wrote in collaboration with Dr. Thomas. He was also for many years editor of the *American Journal of Obstetrics and Gynecology*.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

A SENTENCE FOR REVISION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—With regard to the brief announcement in your last impression that Mr. William Ayres, L.R.C.P. Edin., was tried at the Liverpool Assizes on a charge of manslaughter in pushing a man out of his house, causing him to fall, the result being fracture of the skull, it appeared to me that the case, if correctly reported, was purely accidental, and one, therefore, in which immediate steps should be taken to have the sentence revised and the unfortunate prisoner released.

It is quite conceivable Mr. Ayres might be acting both injudiciously and even illegally in adopting the course he did, which ended fatally. Assuming such to be the case, he would, as I apprehend, in law be responsible for the results of such illegal action; nevertheless, taking this point into due consideration, it is difficult to conceive the law is intended to act with such exceptional harshness as to imprison a medical man, and a British subject to boot, for the result of an accident which was never intended.

I am, Sir, yours truly,

CLEMENT H. SEES.

Queen's Road, Peckham. February 27th, 1902.

The Cancer Hospital, Fulham.

THE fifty-first annual meeting of the governors of this charity was held on Wednesday last, Dr. Alexander Marsden presiding. From the Report of the committee it appeared that during the past year 704 new in-patients were admitted, 1,604 out-patients treated, and the daily average number of beds occupied was 89, being one in excess of last year. The support received during the twelve months, though fully demonstrating that the sympathies of the public were with the institution, was unfortunately insufficient to meet the expenditure, and a sum of £2,249 had to be realised by the sale of capital. The chairman stated that the committee had decided to greatly enlarge the pathological department, for they felt that it was the wish of every supporter of the charity that the Cancer Hospital should be in the forefront of all advancements towards the solution of mysteries surrounding the cause and cure of the disease. An extra expenditure of £800 per annum was all that was anticipated to carry out the scheme, and the chairman earnestly appealed for the funds to enable the committee to put their scheme into practice.

Death from Sulphonal.

MRS. POWER, the wife of Dr. F. Power, of Brixton, died at Bournemouth a few days since as the result of an overdose of sulphonal, supplied by a local chemist. At the inquest a verdict of "misadventure" was arrived at.

Death of Dr. Loudon.

DR. JAMES LOUDON, of Hamilton, who was present at the identification of the body of Dr. Livingstone by Sir William Ferguson and other eminent medical men before its interment in Westminster Abbey, and who was one of the chief mourners on that occasion, died on the 26th ult., at the age of 77. He made the acquaintance of Dr. Livingstone while studying at the Andersonian

College, Glasgow, and remained a staunch friend of the family, the different members of which resided in Hamilton until recently.

Sudden Death of an Accrington Practitioner.

DR. JAMES NIELD COOPER, of Accrington, died on the 26th ult., it is supposed, from an overdose of laudanum. He had been in the habit of taking sleeping draughts.

The Children's Hospital, Dublin.

AT the annual meeting of the friends and supporters of the Children's Hospital, Temple Street, held last week, the report stated that the number of patients treated in the wards in the past year was 1,018, of whom 475 were males, and 543 females. The number treated in the extern department was 8,026. Of the cases treated in the wards, 555 were medical and 463 surgical. Of the medical cases, 338 were cured, ninety-five improved, fifty-one were removed before completion of treatment, five were incurable, and forty died (sixteen of these deaths were caused by meningitis). Of the surgical cases, 463 in number, 351 were cured, sixty-nine were improved, twenty-six removed, two were incurable, and fifteen died. The number of major operations performed was 603. The number of children admitted to the wards and treated at the extern department has greatly increased, although the number of beds was practically the same as last year, but this is explained by the fact that in previous years the hospital was closed for some time during the summer, but during 1901 it was open all the year. After the transaction of some further business the meeting adjourned. We have to sympathise with this valuable charity in the loss they have sustained through the death of Mr. Thomas White, and the failing health of Dr. T. More Madden.

The American Specialists in Ireland.

THE American specialists to whose doings we have already referred, were again brought before the Court at Ennis. Some further evidence was given regarding Madame Lilian's methods of treatment, and Dr. G. Faris was called to give evidence regarding the contents of the medicine bottles they distributed. Eventually the defendants were returned for trial, bail being accepted.

Royal Victoria Eye and Ear Hospital.

AT the annual meeting of the friends and supporters of this institution held recently the annual report stated that in the intern department 1,207 patients, from all parts of Ireland, were admitted to beds, each patient remaining under treatment for about three weeks. On an average 73 beds were occupied every day in the year. In the out-patient department 7,666 patients applied for treatment for the first time, and many others returned for further treatment. An average of 135 out-patients was attended every day by the surgical staff. Six months ago building operations for the new hospital were commenced at Adelaide Road, and are now in progress. The council had ascertained that it was possible, by curtailment, to reduce by £5,000 the amount for which contracts would at first be accepted. The section being built would cost at least £25,000, and of that £5,000 was still needed. The council, therefore, earnestly asked for subscriptions. After the adoption of the report and of some formal motions the meeting terminated. We learn that in addition to at least £9,000, which is immediately required, the new hospital will also eventually require £25,000 more. We trust that the amount required will be fully subscribed.

Suicide of a Medical Student.

MR. CHURCHILL BRADON CLARKE, a student of the Westminster Hospital, committed suicide last week by cutting his throat. He had recently failed to pass an examination, but no adequate reason for the act was forthcoming. At the inquest a verdict of "temporary insanity" was returned.

Plague in Sydney.

THERE were fifty cases of plague in Sydney last week, and among the victims are two young ladies belonging to the Charles Arnold Company. A rat drive on a large scale has been organised, but it is suspected that mosquitoes, fleas, and other parasites also contribute to spread the disease.

Notices to Correspondents, Short Letters, &c.

✉ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a distinctive signature or initials, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

CAPTAIN B.—The question of paying the usual fee to medical witnesses at inquests irrespective of their holding office to a hospital or infirmary, has been raised over and over again, but for some reason the Local Government Board holds to the view that no such fee should be paid. The point, as you suggest, is one which ought to be raised in Parliament at a convenient season.

M. O. H.—An easy way of killing rats on shipboard without damaging the cargo is to fill the hold with carbonic acid gas, a process which is easy of accomplishment and is reported to be very effectual. Another advantage is that it is easy to pump in fresh air when the lethal work has been done.

MR. S. (Croydon).—Your communication has been received and inquiries have been set on foot in accordance with your suggestion.

DR. ELMORE.—We are unable to utilise your contribution, which has a too markedly political bias for our columns.

S. L. C.—The difficulty seems to arise from the vagueness of the terms used to describe the injury. Under the circumstances it would be prudent to give the claimant the benefit of the doubt, which would doubtless be the view taken by a jury if the matter were taken into Court.

Meetings of the Societies, College Lectures, &c.

LONDON.

WEDNESDAY, MARCH 5th.

OBSTETRICAL SOCIETY OF LONDON (30, Hanover Square, W.)—8 p.m. Specimens will be shown by Dr. C. Berkeley, Dr V. Bonney, The President (Dr. Horrocks), and Dr. Boxall. Paper:—Dr. R. G. McKerron: Suppression of Urine after Labour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. F. G. Parsons: The Blood-vessels of Mammals in Relation to those of Man.

THURSDAY, MARCH 6th.

HARVEIAN SOCIETY OF LONDON (Stafford Rooms, Titchborne Street, Edgware Road, W.)—8.30 p.m. Clinical Cases will be shown by Dr. Cantley, and others. Paper:—Mr. P. L. Daniel: Some Rare Cases of Sarcoma of the Thyroid.

BORTHEN SOCIETY (30, Hanover Square, W.)—8.30 p.m. Exhibition Evening. Paper:—Dr. B. Blacker: Localisation, with demonstration of a Simple Direct Reading Apparatus.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital).—4 p.m. Demonstration of Clinical Cases.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 p.m. Dr. G. F. Still: Some Abnormal Physical Conditions in Children. (Goulstonian Lecture.)

FRIDAY, MARCH 7th.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich Road, S.E.)—8.45 p.m. Clinical Cases and Pathological Specimens will be shown or Notes read by Dr. Teagood, Mr. C. Williams, the President, Dr. L. Williams, Dr. J. Donelan, Dr. Herschell, Mr. E. V. Donnellan, Dr. Peacock, Dr. Henry, and Mr. Caesar. Living Cases will be taken first.

SOCIETY OF ANESTHETISTS (20, Hanover Square, W.)—8.30 p.m. Clinical Evening. Followed by a General Meeting to consider the Addition to Rules.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Prof. F. G. Parsons: The Blood-vessels of Mammals in Relation to those of Man.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8.30 p.m. Clinical Meeting in the Society's rooms. Mr. Keetley, Mr. Edwards, Mr. McAdam Eccles, Dr. Ball and Dr. Saunders will show Cases.

SATURDAY, MARCH 8th.

MEDICAL SOCIETY OF LONDON (Whitehall Rooms, Hotel Metropolitan).—7.30 p.m. 129th Anniversary Dinner. Dr. W. H. Allchin (President) in the chair.

DUBLIN.

THURSDAY, MARCH 6th.

ROYAL COLLEGE OF SURGEONS.—Council Meeting.
DUBLIN UNIVERSITY BIOLOGICAL ASSOCIATION, Front Hall, Trinity College, 8.30 p.m.

FRIDAY, MARCH 7th.

ROYAL COLLEGE OF PHYSICIANS.—4.30 p.m. Monthly Meeting.
ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Medicine, College of Physicians, 8.30 p.m. Papers:—Dr. Finny and Dr. Edward Watson: Cases illustrating the Aid of X-rays in Intrathoracic Disease. Dr. W. S. Haughton: The Use of X-rays in Medical Diagnosis. Mr. E. F. Tobin: Some Medical Aspects of Four Consecutive Cases of Perforated Gastric Ulcer Successfully Operated On. Dr. Parsons: A Case of Ascending Paralysis. Dr. O'Carroll: Two Cases of Ascending Paralysis.

Appointments.

BEYERS, EDMUND C., M.A., M.B., B.Ch.Oxon, M.R.C.S., L.R.C.P., House Physician to the Radcliffe Infirmary, Oxford.

CAREY, C. DE L., B.A., B.C.Cantab., Second House Surgeon to the East Suffolk Hospital, Ipswich.
COLLINS, J. C., M.B., B.Ch., B.A.O.T.C.D., Medical Superintendent of the Provincial Hospital, Auckland, New Zealand.
COLLUM, E. W., L.R.C.P.Lond., M.R.C.S.Eng., Anaesthetist to the Charing Cross Hospital.
COOPER, EMOR E., M.B., Ch.B.Vict., House Surgeon to the Devonshire Hospital, Buxton.
DOYLE, ANDREW ALOYSIUS, F.R.C.S.Irel., Medical Officer at Roma, Queensland, and Visiting Surgeon to the Prison.
JEFFERISS, FREDERICK B., M.R.C.S., L.R.C.P., Assistant Physician to St. Bartholomew's Hospital, Rochester.
O'CONNOR, ARTHUR CHARLES, M.B., M.Ch.Syd., Government Medical Officer at Bulli and Coalcliff, New South Wales.
BATNER, DAVID CHARLES, F.R.C.S.Eng., L.R.C.P.Lond., Lecturer on Practical Midwifery at University College, Bristol.
SHARP, ELLEN M., M.B.Lond., Senior House Surgeon to the Victoria Children's Hospital, Hull.
SWAYNE, WALTER CARLESS, M.D.Lond., L.R.C.P.Lond., M.R.C.S., Professor of Midwifery at University Colleges Bristol.
TOD, HUNTER F. M.A., M.B., B.C.Cantab, F.R.C.S., Surgeon to the Throat and Ear Department of the Paddington Green Children's Hospital.
VAN PRAAGH, HAROLD, M.D.Lond., Casualty Physician at St. Mary's Hospital.
WHITE, E. A., M.D.R.U.I., Medical Officer to the Isle of Thanet Joint Hospital Board.

Vacancies.

Bradford Poor-law Union.—First Resident Assistant Medical Officer. Salary £125, with prescribed rations, apartments and washing. Applications to Thos. Crowther, 22, Manor Row, Bradford.
Central London Sick Asylum District.—Assistant Medical Officer. Salary £130 per annum with board and residence. Applications to Fredk. W. Bailey, Clerk's Office, Cleveland Street Asylum, Cleveland Street.
Children's Hospital, Forest House, Nottingham.—House Surgeon. Salary £100, with board and residence. Applications to A. F. Kirby, St. Peter's Church Walk, Nottingham.
County Asylum, Freetwith, Manchester.—Junior Assistant Medical Officer. Salary £150, with board, furnished apartments, and washing. Applications to the Medical Superintendent.
Dorset County Hospital, Dorchester.—House Surgeon. Salary £100. Reside and board in the hospital. Applications immediately to the Chairman of the Committee.
Durham County Asylum.—Junior Assistant Medical Officer. Salary £150, with board, apartments, laundry, and attendance. Applications to Medical Superintendent, Durham County Asylum, Winterton, Ferryhill.
East Sussex County Asylum, Hayward's Heath.—Second Assistant Medical Officer and Pathologist. Salary £175 per annum, with board, lodging, washing, and attendance. Applications to the Medical Superintendent.
Manchester Royal Infirmary.—Honorary Assistant Physician. Applications to W. L. Saunders, General Superintendent and Secretary. (See Advt.)
Manchester School Board.—Medical Officer. Salary £250 per annum. Private practice allowed. Full particulars of the Clerk of the Board. (See Advt.)
Metropolitan Asylums Board.—Male Assistant Medical Officer. Salary £150 per annum, with rations, lodging, attendance, and washing. Applications immediately to the Office of the Board, Embankment, E.C.
Royal National Hospital for Consumption and Diseases of the Chest, Ventnor.—Assistant Resident Medical Officer. Salary £100 per annum, with board and lodging in the hospital. Applications immediately to the Secretary, 34, Craven Street, Charing Cross, W.C.
South Africa.—Junior Resident House Surgeon for Hospital in South Africa. Salary £250, with board and lodging. Applications to H. Chaplin and Co., 9, Gracechurch Street, London.

Births.

FAWCETT.—On Feb. 25th, at 13, Millfield, Folkestone, the wife of Edward Fawcett, M.D., of a daughter.
KENDALL.—On March 2nd, at Chiddingfold, Surrey, the wife of Nicholas Fletcher Kendall, M.R.C.S., L.R.C.P., of a son.
NOWLAN.—On Feb. 20th, at Balbriggan, the wife of Dr. F. B. Nowlan, of a daughter.
POWELL.—On Feb. 28th, at 37, Brunswick Gardens, London, W., the wife of Llewelyn Powell, M.A.Cantab, M.B., of a daughter.

Deaths.

ELLIOTT.—On Feb. 27th, at 53, Clarence Parade, Southsea, Ernest Elliott, M.D., late R.N., aged 84.
HENINGWAY.—On Feb. 25th, at East Twickenham, Elizabeth Greenfield, widow of Henry Johnson Heningway, M.D., of Dewsbury, Yorkshire.
KENT.—On Feb. 27th, at Bournemouth, Robert Thomas Kent, of Eastbach Court, Coleford, Gloucestershire, F.R.C.S., M.A. Oxon., recently Professor of Anatomy at St. Mungo's College, Glasgow, aged 48.
LAPTHORN.—On Feb. 26th, at Bletsoe House, Littlehampton, Charles Albert Laphorn, F.R.C.S.E., son of Edwin Laphorn, J.P., of Fairthorne, Gosport, in his 41st year.
POWELL.—On March 1st, at 37, Brunswick Gardens, W., of pneumonia, Nina Marion, wife of Llewelyn Powell, M.A.Cantab, M.B., aged 38.
SIMPSON.—On Feb. 26th, at 7, Darnley Road, Holland Park Avenue, London, W., Maxwell Simpson, M.D., LL.D., F.R.S., in his 87th year.

Original Communications.

AN INSTRUCTIVE CASE OF INHERITED SYPHILIS.

By SYDNEY STEPHENSON, M.B., C.M.,

Ophthalmic Surgeon to the Evelina Hospital and to the North-Eastern Hospital for Children.

THE subject of this communication, John O., *et. 8*, first fell under my notice on January 5, 1893. His face was characteristic of inherited taint. For example, his forehead was square and "bossy"; rhagades were present at the angles of his mouth; his upper central incisors were dwarfed and notched at the cutting edge; and the lad was thin and of delicate appearance. Sight equalled about one-fifth of the normal. The cornea showed neither opacities nor fine, parenchymatous vessels. There were several small nodules attached to the edge of the iris due to excessive localised development of the uveal layer, the so-called *ectropion uveæ*. Each fundus oculi manifested extensive pigmentary and atrophic changes, as well as lines of pigment along many of the small, peripheral retinal vessels. This condition of choroido-retinitis accounted for the imperfect sight. It was further noted that the upper lids tended to droop, although whether this was pathological or not there was no means of deciding.

A few months later (September, 1893) the lad's right eye became red, watery, and sensitive to light. Upon examination, the lower third of the cornea was found to be occupied by deep-seated interstitial opacities, while the upper two-thirds showed fainter changes. An atypical "salmon-patch" existed at the lower part of the limbus conjunctivæ. The keratitis was treated by atropine locally, and generally by the inunction of one drachm of mercury ointment night and morning. For some little time the eye continued to improve, but on January 11th, 1894, a number of adhesions were found between the iris and the anterior capsule of the crystalline lens, thus showing that inflammation of the iris was present. It was then determined to try what effect would be produced by the subconjunctival injection of a soluble salt of mercury. Accordingly, on January 23rd four minims of a 1-1000 solution of corrosive sublimate were injected beneath the conjunctiva of the inflamed eye. The injections were repeated on eight occasions between January 23rd and April 16th, 1894. Meanwhile it was found that the changes present in the fundus of the right eye were advancing, and that they had become complicated with the presence of many fine opacities in the vitreous humour. The last five injections of sublimate were therefore made beneath the conjunctiva of both eyes. On April 25th the left cornea, hitherto unaffected, showed a single parenchymatous deposit in its lower segment. The eye continued to get worse, and

became painful. On May 14th the left cornea, except as regards its central part, was almost wholly opaque, and two crescentic "salmon-patches" were present—one up and out, and the other down and in, each being about 2 mm. across the widest part. Sight: doubtful perception of light. The tension of the eyeballs was normal. On May 30th the left cornea was wholly opaque, and the vascular "salmon-patches" formed a continuous ring around the clouded cornea. The right cornea had suffered a relapse, and was more opaque than ever. Each knee-joint was slightly swollen and contained fluid. The mercurial inunctions were stopped, and five grains of potassium iodide were given thrice a day. On June 2nd there was much pain in the left eye. The opaque cornea was encircled by a vascular area, 2 mm. wide; the corneal epithelium was clear. No perception of light. June 13th.—Left eye, tension minus 1; no perception of light. The appearance was most peculiar, namely, an irregular area of the cornea, 5 mm. at its widest part, was of an opaque, whitish-yellow hue, and this was everywhere surrounded by a zone of vascular tissue, a confluent "salmon-patch." Viewed from the side, the cornea projected forward, cone-wise. The blunt apex of the cone was formed by opaque cornea, and the sides of the cone by the vascular patch. It was noted that the patient had become rather deaf. June 19th.—The right cornea is getting worse. A portion of the grey, opaque, central area of the left cornea is ulcerated. (a) The deafness is increasing. June 24th.—The knees are somewhat better to-day, but the ankles have become swollen. June 26th.—There is less redness and bulging of the left cornea. The central greyish area shows a small, dark spot. Descemet's membrane. Tension minus two. Deafness increasing. July 17th.—Right eye: Slight patchy redness around the cornea; pupil, of medium size, can be seen dimly through the cloudy cornea; tension slightly minus. Left eye: The cornea looks flattened, but no details of the deeper structures can be made out through it; the "salmon-patch" has cleared. The central part of the cornea is now occupied by a white patch, of irregular outline. Deafness is increasing, but the lad is still able to hear a question shouted loudly in his ear. August 9th.—The eyes are now practically free from redness. For several days past the patient has been the subject of delusions. Thus, he imagines that another lad is thrashing him, that the ward nurse treats him cruelly, and that he is being starved. With reference to the last point, it may be as well to state that he was, in point of fact, on chicken and port wine in addition to his ordinary diet. August 27th.—Since the last note the delusions have become very pronounced. The patient is troublesome, uses vile language, insists upon getting

(a) While it is undoubtedly true that ulceration is seldom seen in interstitial keratitis, yet I have notes of five cases where that complication was present.

to the second and third equivalent quantities of cacodylates. One of the latter was oxidised in a special manner with mineral acids, so as to set free the arsenic. All three were then examined by Marsh's process, when only the first and third gave the reaction of arsenic, the second, containing unoxidised cacodylate, yielding no response. Similarly the urine of patients taking cacodylate gave no reaction on Marshing, while after oxidation it gave a very marked deposit of metallic arsenic on the walls of the tube. It, therefore, appears that the cacodylates pass through the body in a state of stable combination, with the arsenic so firmly locked up that it cannot be dissociated to form pharmacologically active substances, and thus exert the toxic and therapeutic effects of the usually employed compounds of arsenic. It is, in fact, analogous to the action of cyanogen, which, active in many of its preparations, yet enters into such stable combination as the ferro and ferri-cyanides as to be entirely inert. Therapeutically useless as he believed cacodylates to be, they also possessed certain disadvantages and could not be regarded as entirely harmless. The administration of the drug had almost invariably to be discontinued on account of the disturbance of the alimentary duct which it produced, while the garlic odour was also highly repugnant to most patients. It was, indeed, said that in order to secure the best results cacodylate ought to be given subcutaneously; if this were so, it was in itself highly disadvantageous in a drug which generally had to be continued over prolonged periods, and he had also found that not even by this means could gastric disturbance be avoided.

The Hunterian Lectures

ON THE ANATOMY, PHYSIOLOGY AND PATHOLOGY OF THE IMPERFECTLY DESCENDED TESTIS. (a)

By W. McADAM ECCLES, M.S.LOND.,
F.R.C.S.,

Hunterian Professor of Surgery; Senior Assistant Surgeon, West London Hospital; Assistant Surgeon, City of London Truss Society; Examiner in Anatomy to the Society of Apothecaries, &c.

ABSTRACT OF LECTURE II.

PHYSIOLOGY.

MR. PRESIDENT AND GENTLEMEN,—Nearly all authorities are agreed that the testis which has not reached its normal position in the scrotum is generally functionless—at least, in so far as the formation of spermatozoa is concerned. While, therefore, there is no doubt that this belief is true in the vast majority of instances, yet there are persons whose testes, although arrested or ectopic, are nevertheless capable of producing well-formed and active spermatozoa. This fact has been indubitably proved by the microscopical examination of the semen which has been ejaculated and of the lining epithelium of the tubules of the glands themselves, in addition to the evidence of the procreation of children.

Double arrest or ectopia associated with want of development of the testes as a rule implies sterility on the part of the man, although he may be perfectly virile. There is also some real doubt as to whether a testis arrested at birth, but brought down in early life into the scrotum ever so develops as to become the seat of spermatogenesis. A few cases are on record in which this has been stated to have occurred, but the facts given do not support the assertion strongly. But while the chief fault of the imper-

fectly descended testis may be its inability to produce active spermatozoa, there are other conditions so closely associated with arrest or displacement of the organ that they require some description. There would appear to be some relationship between the general growth and development of the body in the male and a proper descent of the testis, or, to put the same statement in slightly different language, many instances of want of general growth of the body are accompanied in the male by an arrest of the testes. It would seem that either the fully-descended and developed testis is sufficient to promote bodily growth, that it has in reality at present some obscure qualities or functions that render it capable of playing an important rôle in the organism in spite of its fellow being functionless, or that, on the other hand, the arrested gland does of itself supply its quota towards the full development of the individual. If the former view is the correct one it might be urged that the normal testis, in order to supply the full amount of what is needful for growth of the body, ought to show signs of hypertrophy. Yet a size of the normally placed organ greater than it should be in a person of corresponding age and development is but rarely seen in the human subject. In animals, on the other hand, there seems to be more evidence of such a compensatory hypertrophy. This is particularly the case in the stallion. Sometimes in this animal the descended organ may reach twice the bulk of a normal testis in a horse of the same age and size. Because, therefore, in the human subject true hypertrophy of the fully-descended testis when its fellow is arrested is a comparatively rare condition it still remains to determine whether the completely descended and fully-developed organ, although not larger than normal, is capable by itself of supplying the needed stimulus for adequate bodily growth, or whether the arrested testis that is also present has to subscribe its share towards the same result.

It has been shown that although in instances of double arrest of the testes both organs may be wholly incapable of producing spermatozoa, yet the owner of them may acquire full virile power, but will remain for ever without the ability to procreate. The arrested glands not infrequently have large numbers of these well-defined interstitial cells, and it is possible that they have an important function at the onset of puberty. They may have the duty of producing what is now so generally called the "internal secretion" of the organ. This substance, whatever it may be, probably plays an important rôle in the development of the body, for without its presence much of the normal growth may be lost or the usual changes that occur at puberty may be profoundly modified.

Returning again to the theory that in some instances the association of imperfect descent of the testes with a failure in perfect growth may be due in reality to some common cause, cretinism is perhaps the best example of such. In male cretins it is extremely rare to find either of the testes within the scrotum, and it is equally rare to find them at all developed, and although I have not as yet had the opportunity of examining the testis of a cretin by the microscope, I should expect that the interstitial cells are altogether wanting in their development. Thus it may be stated shortly that whereas there are found in the testis two distinct types of cells, one those needed for the formation of spermatozoa, and the other probably, though it cannot at present be affirmed positively, those required for the production of an internal secretion, failure in the development of both these types of cells will as a rule lead to failure in the proper bodily growth of the individual, but development of the interstitial

(s) Delivered before the Royal College of Surgeons of England on Feb. 26th, 1902.

cells, even though there are no sperm elements, will allow the possessor to become virile but yet to remain sterile.

Many cases are on record in which imperfect descent of the testis has been accompanied by actual bodily deformities. Among the more interesting and important of these are:—1. The occurrence of incomplete transition with the absence of one kidney. In one such case a sarcoma of the arrested testis actually produced a fatal result by extension to the sole renal organ present. 2. The co-existence of talipes, of spina bifida, and of cleft palate is by no means rare. 3. Non-descent of the cæcum into the right iliac fossa is occasionally discovered. The connection of the passage of the cæcum into the region which it normally occupies and the migration of the testis into the scrotum have much in common. In those instances where the cæcum has failed to reach the iliac fossa the right testis, and sometimes also the left, has not usually passed beyond the confines of the abdomen. As has been pointed out, the gubernaculum testis has anterior attachments to the cæcum, &c., and these share probably in bringing about some of the movement of the bowel. In those instances in which the cæcum has remained higher than it is naturally there has been an arrest in its so-called descent, while in those cases in which there exists a congenital cæcocolle there has probably been an excess of the normal traction. 4. Ectopia vesicæ is almost always when it occurs in the male associated with imperfect descent of the testes, which, as a rule, lie in pouches on either side of the extroverted bladder. Not infrequently there is a hernial protrusion at the same time into the processus vaginalis of the arrested glands. 5. In one instance at least there has been a double penis associated with imperfect descent of the testes. There does not appear to be any evidence that arrest of the testes is accompanied by a failure in the development of the tonsils, just as there is none to justify the belief that has been held by some that excision of the tonsils is liable to be followed by atrophy of the testes.

PATHOLOGY.

Inflammation of the Imperfectly Descended Testis.—The testicle which has not reached the lowest limit of the scrotum, or which has passed into abnormal positions, is liable to inflammation arising from the same causes as the inflammatory conditions of the normally descended organ. But, in addition, the site of the testis when arrested or ectopic in itself renders it prone to become inflamed from reasons other than those operating upon the normally placed gland. Inflammation of the imperfectly descended testis may be due, therefore, to (1) traumatism; to (2) extension of inflammation from the urethra; to (3) secondary inflammation in certain cases of parotitis (in all of these the inflammation is of an acute nature); to (4) deposit of the tubercle bacillus; or to (5) syphilitic infection (in both of these it is usually of a chronic nature).

Traumatic Inflammation: Causation.—Inflammation due to traumatism is peculiarly the misfortune of the testis which is abnormally situated. A testis hanging from a normal cord in the lowest part of the scrotum, although apparently exposed to many and grave dangers, is in reality comparatively seldom actually damaged, for it is well able to get out of harm's way. It is so mobile that it slips aside almost at the approach of violence. Not so the testis which hangs high in the scrotum or just below the superficial ring, often from a short, altogether unyielding, cord, or the gland which is retained in the inguinal canal. When it has only passed out of the canal but a short way the testis is so placed as to be constantly open to receive blows and various forms of harmful

pressure, which it is unable to avoid in the manner that its normally placed fellow can do. Many a time the delicate and sensitive testicular tissue is pressed backwards against the totally unyielding body of the os pubis, only to result in a sharp attack of acute orchitis. It is here also, outside the inguinal canal, but not in the scrotum, that the imperfectly descended testis is certain to be injured by the pressure of the pad of a truss that has been improperly applied. When an inguinal hernia accompanies a testis found just below the superficial abdominal ring, the pad of the truss which is to control it should be placed over the site of the inguinal canal and altogether above the level of the body of the os pubis. Here it will rest only upon soft tissues, and the testis will be in no way exposed to injurious pressure. In like manner the adjustment of a truss to a bubonocoele with the testis in the inguinal canal will cause no harm, as a rule, if the testis is allowed to slip away to one or other side of the pad. But it may be markedly irritated in this position if a truss with a so-called horse-shoe or forked pad is applied. Fortunately, the testis has the good sense not to remain within the trap that is so placed to retain it and thus escapes injury; but should it happen to be squeezed in the restricted area prepared for it an attack of inflammation is almost certain to result. Again, with the testis in the canal damage may accrue if a truss with too strong a spring is applied, or from the pressure of an instrument the spring of which has a too-marked antero-posterior curve, as so often seen in badly constructed trusses. Inguinal inclusion is also a cause of inflammation owing to the fact that strong muscular efforts on the part of the patient will produce sufficient pressure upon the organ to set up actual injury. In many other cases the application of a truss is in reality a prophylactic measure, for it will occasion the retention of the gland within the abdomen and thus keep it to a great extent out of danger.

There is another manner in which a testis in the inguinal canal may be damaged. Supposing that the gland is at the lower part of the canal, and hanging from a fairly lax cord, one that allows of a certain amount of play in an up-and-down direction, a sudden muscular effort, such as the lifting of a heavy weight, may lead to the extrusion of the organ through the superficial abdominal ring, the pillars of which during the passage become separated from one another and approximate after the descent. It will thus come about that undue pressure may be exerted upon the spermatic cord, as well as possibly some actual injury to the testis in its transition. Very severe pain, sometimes enough to cause fainting, is occasioned and acute inflammation rapidly supervenes. This accident, although in some points resembling that of torsion of the spermatic cord, is distinct from that lesion and may be several times repeated, provided that the testis is withdrawn again within the limits of the canal.

Inflammation of the imperfectly descended testis consequent upon traumatism may occur at all ages, but is most common in young adults.

The prognosis of traumatic inflammation of the imperfectly descended testis is a grave one so far as the organ itself is concerned. Such an inflammation is nearly always the forerunner of complete atrophy of the gland, so that should it have possessed any vestige of function previously to the attack this will be lost entirely subsequently. If the disorganisation of the testicular tissue is not absolute after the primary inflammation a second attack is almost sure to occur and lead to total destruction or the conversion of the gland into a fibrous mass. These repeated attacks of inflammation will render the organ a source of great annoyance to the sufferer, and may be even of danger to him. It is rare for suppuration

to take place in the ordinary traumatic inflammation, just as it is also uncommon when the normally placed testis is similarly affected.

Although it is undoubted that atrophy may, and often does, follow upon inflammation of the arrested testis, yet it is open to considerable uncertainty as to whether malignant disease is ever attributable to the same lesion. Irritation and inflammation of the imperfectly descended gland may possibly in some rare cases initiate such changes in the testicular tissues, so far as its embryonic constituents are concerned, as to bring about the incidence of a new growth. In a few instances where the testis has been found in the inguinal canal and has been the seat of inflammation, peritonitis has been set up within the abdomen, owing to the fact of the communication between the processus vaginalis and the general cavity of the peritoneum.

Gonorrhœal inflammation of the arrested organ is apt to be more severe than that occurring in a testis which is in the scrotum. Where the testis remains within the abdomen peritonitis may supervene owing to the extension of the gonorrhœal inflammation to the adjacent serous membrane. In a few cases in which the body of the testis has been fixed in the inguinal canal and the epididymis has passed into the scrotum together with the vas, a gonorrhœal infection has occasioned a swelling and tenderness in the latter region, and perhaps no discomfort above Poupert's ligament. A fact which is worthy of attention is that it is by no means infrequent to find a specific epididymitis of the fully descended organ while its arrested fellow escapes sharing in the inflammation. As in the traumatic inflammation of the imperfectly descended testis atrophy may occur, so it may follow a gonorrhœal infection of the same, and is probably more generally the termination of the lesion than it is when the organ is normally placed.

An orchitis of an arrested testis may occur during an attack of acute parotitis. In such instances, as is the case in the similar affection of the fully descended organ, the inflammation is prone to be very severe and for the time being alarming. Atrophy subsequently is, moreover, very common as a sequela.

Torsion of the cord of an imperfectly descended testis.—Torsion of the spermatic cord may occur in connection with the fully descended or imperfectly descended testis. Nearly 50 per cent., however, of the recorded cases are those in which the testis has been arrested, and in the other half there is usually some abnormality of the testis or its adnexa. Almost all viscera within the abdomen which possess pedicles are at times the seat of axial rotation, and many tumours which form within the abdomen are also liable to have their pedicles twisted. There are a number of predisposing causes which possibly act in bringing about torsion. Imperfect descent of the testis, an abnormally long mesorchium, a practical absence of a mesorchium, action of the gubernaculum testis, a congenital twist of the cord, a roomy tunica vaginalis, and a flattened condition of the imperfectly descended organ, are all factors predisposing to torsion. There are two important peculiarities that may be present in the testis which has not reached its proper habitat. These are an abnormally long mesorchium, and the existence of two cords supporting the testis, the one consisting of the vessels, the other of the vas deferens. Frequently the two conditions are found at one and the same time. The reason of this anatomical arrangement is not far to seek. The body of the testis has its own blood-supply, and these vessels lie in the plica vascularis, which will then form one cord or part of the mesorchium, while the epididymis and the vas have an altogether separate origin, and therefore a different blood-supply, and they consequently tend in some cases to form a distinct cord, which may become itself

the site of torsion. It thus comes about that the imperfectly descended testis is less firmly attached than is the normally situated one, and there is a liability, if any exciting cause occur, for axial rotation to take place. Probably an absence of a mesorchium is a condition which is seldom, if ever, present. It is extremely doubtful whether the gubernaculum can ever exercise any influence in bringing about torsion. It has been suggested that as the outcome of intra-uterine peritonitis a congenital twist may be given to the testis in its descent, and that later this may be aggravated by an exciting cause of torsion being added to it. A roomy tunica vaginalis would certainly give more space for the occurrence of a twist. To sum up, it is probable that partial descent with a freely movable testis is the chief predisposing cause of torsion of the spermatic cord.

As exciting causes may be mentioned a muscular effort, a mechanical twist, the action of the cremaster, the application of a truss, attempts at the reduction of a hernia by taxis, and possibly the enlargement of the organ at the approach of puberty. Others have thought that a primary thrombosis of the vessels of the pampiniform plexus exists, and that torsion is merely secondary to this. A sudden muscular effort with the testis lying in the inguinal canal is the history of many cases of torsion. As soon as the vessels of the cord undergo a rotation around their longitudinal axis the circulation of blood within them is seriously interfered with. The onset of torsion more markedly affects the thinner-walled veins than the artery, with the result that while the blood is pumped in through the latter it cannot properly return through the former. The consequence of this is a rapid and extreme turgescence of the veins of the pampiniform plexus and great congestion of the whole of the parts from which they derive their blood. It is this over-full state of the vessels that leads to the agonising pain from which the patient suffers. Soon the testis becomes greatly increased in size, often to twice, or even thrice, its original magnitude. Occasionally it is only the epididymis that is enlarged, the body of the testis remaining almost its usual size. This will be the result of a twist only of that cord which carries the vessels of the epididymis and vas.

If the congested testis is exposed by an incision it will be found to be bluish-black in colour, not unlike a ripe purple plum, and somewhat like very deeply congested gut. This discolouration may in some instances be visible even through the skin. A certain amount of fluid, usually blood-stained, may transude the distended vessels into the cavity of the tunica vaginalis. Sometimes the vessels actually give way under the pressure to which they are subjected, and pure blood is thereby extravasated. It is interesting to note that there may be a comparatively early invasion of the congested tissues by bacteria, both cocci and bacilli, but possibly only in the cases in which an accompanying hernia has allowed intestine to lie in juxtaposition. These micro-organisms may lead to suppuration in the sloughing organ or to the formation of pus in the wound after the removal of the gland.

For the integrity of the gland torsion necessitates a very grave prognosis. Even one attack of rotation, and that only permitted to last quite a short while, say but a few hours, has been demonstrated to lead to atrophy of the testis. Repeated attacks unquestionably tend to eventual disorganisation. Torsion produces atrophy. Torsion with infection by bacteria leads to true moist gangrene.

SIR WILLIAM DALBY, F.R.C.S., is leaving London for a journey in the East.

THE REGISTRATION OF DISEASE. (a)

By NINIAN McINTIRE FALKNER, M.D. Dubl.;
F.R.C.P.I.,

Dipl. in State Medicine, Univ. Dubl.; Medical Superintendent of
Statistics in the Registrar-General's Office, Dublin.

THE registration and notification of sickness was brought before the public by Dr. Arthur Newsholme in a paper read before the Royal Statistical Society of England in the year 1895, from which I have borrowed the following abridged history. In this paper he pointed out that mortality is not necessarily a correct index to the morbidity of a community. Mortality statistics necessarily ignore everything that precedes the close of life:—

The history of the attempts which have been made to establish a national registration of sickness appears to have originated with Mr. John Bellers in the beginning of the eighteenth century. It was again urged in 1732 by Dr. Clifton, Physician to the Prince of Wales, with special reference to hospitals. Dr. Rumsey, in 1844, in his evidence before the Medical Poor Relief Committee of the House of Commons, suggested a comprehensive plan for the uniform registration of the sickness which affects the poorer classes. Dr. Liddle, subsequently Medical Officer of Health for Whitechapel, proposed amended forms for the weekly medical returns, made by their medical officers to the boards of guardians, and the utilisation of these returns in general sanitary inquiries. About the same time it was suggested by Sir B. W. Richardson that these returns might easily, with a few obvious modifications, be employed as a basis for the national registration of disease, especially as a record of epidemics. This article further suggested the appointment of a Registrar-General of Diseases in London as the central authority, to whom the district returns after local use should be forwarded for digest and publication. Sir B. W. Richardson was, however, the first to carry any scheme for notification and registration of sickness into actual practice. The work he had performed with his forty-four volunteer observers was tabulated in the "Journal of the Public Health and Sanitary Review" for 1855. In 1857 the work was taken up by the Metropolitan Association of Health Officers. The returns were furnished voluntarily and gratuitously by the respective medical officers of hospitals and dispensaries—the general Board of Health undertaking to print the returns.

In 1858 this effort collapsed. In 1860 Dr. Ransome organised an effort by means of the Sanitary Association of Manchester and Salford. In this report the number of deaths among the cases reported were stated. From this the work was taken up by the Social Science and the British Medical Association as the result of a paper read on the subject by Dr. Rumsey. A committee was formed of the former association, composed of Drs. Acland, Farr, Greenhow, Southwood Smith, and Messrs. John Simon and Edwin Chadwick.

At a meeting of the Lancashire and Cheshire Branch of the British Medical Association, held on October 24th, 1862, it was resolved that a sub-committee be appointed "to consider and report on the best means of carrying out the registration of disease in large towns." A committee of the whole British Medical Association was appointed in 1865, at the instance of Dr. Ransome, and for ten years he prepared valuable reports.

In Dublin the British Medical Association adopted the form proposed by the Committee appointed in 1868 for the uniform registration of disease. In 1869 Sir B. W. Richardson headed a deputation who waited upon the President of the Poor-law Board. Mr. Goschen received this Committee, and agreed with them on the importance and utility of the work, but pointed out that care should be taken not to impose additional labour on the Poor-law officers, and that the nomenclature of disease used should be uniform. The Committee recommended that a deputation of

the British Medical Association should also seek an interview with Mr. Goschen, and should be instructed to state: (1) The importance to the public and to science of such a registration of disease; (2) the success of the scheme adopted by this Association; (3) that the method adopted provides for a uniform nomenclature of disease; (4) that it need not entail any additional labour on the Poor-law medical officers; (5) that the appointment of registration officers (medical) would not only facilitate the registration of disease, but would greatly improve other sources of State Medicine.

Whatever may be said as to the possibility of this elaborate, ambitious, and perhaps inconsiderate scheme, as regards the overworked medical practitioners, on whom was placed the burden of performing the work as a voluntary tribute to the State, those, and the others who preceded them and helped them, no doubt deserve the credit of the Act which was passed in the year 1889.

Clinical Records.

EDINBURGH ROYAL INFIRMARY.

Case of Tabes with Acutely Developed Ataxia, in which great and rapid improvement had resulted from Frenkel's Plan of Treatment. (a)

Under the care of BYRON BRAMWELL, M.D., F.R.C.P.,
F.R.S.E.

The patient was a married man, æt. 35. For five years he had been a barman, and for sixteen years previously a ship steward. He was admitted to the Edinburgh Royal Infirmary on January 22nd, 1902, because of inability to stand and walk, but had enjoyed good health until the present illness commenced. He absolutely denied syphilis and gonorrhœa. There was no suspicion of alcoholic excess; his average allowance of alcohol was four glasses of beer per week; he did not take more than twelve glasses of whiskey per annum. He was not a heavy smoker. For six months before the inability to walk developed, he had had some, but only slight shooting pains in the legs, more especially the left leg, which was sometimes swollen at night, the result, he thought, of varicose veins. He had occasionally experienced a dull pain in the back and some little difficulty in micturition, having to "force" a little to get the urine away.

The inability to walk developed rapidly on January 13th, 1902. For a fortnight before this date he had felt some stiffness and pins and needles in his legs and feet, but had no difficulty in walking in the dark. He was in the habit of walking from his place of business to his house, a distance of about a mile, every night at twelve o'clock. On Sunday, January 12th, he walked three miles. On Monday, January 13th, he had great difficulty in walking from one room to another. On January 14th he was quite unable to stand or walk.

On examination it was found that the inability to stand and walk was due to ataxia. There was no paralysis; the muscularity of the legs was good; the movements of the legs were wildly ataxic; there was no ataxia in the arms. When the eyes were closed, there was total loss of the sense of position, both during and after passive movements in the lower extremities. Occasional shooting (lightning) pains were complained of in the legs (thighs and calves). There was some varicosity of the veins of the left leg. The left calf was 12½ inches, and the right 11½ inches; the patient was a short, spare man.

The knee-jerks and Achilles-jerks were completely absent even after reinforcement; the deep reflexes in the upper extremities were present, but not exaggerated; the jaw-jerk was present. The direct muscular excitability of the anterior and posterior leg muscles and of the quadriceps group was slightly increased; there was no myodynia contraction. The plantar reflex was very active in both legs, the toe movement being flexion; the cremasteric reflex was absent on both sides; the abdominal reflex was present, but slight.

(a) An abstract of the Presidential Address delivered at the Opening Meeting of the Section of State Medicine of the Royal Academy of Medicine in Ireland, Feb. 14th, 1902.

(a) Case shown before the Edinburgh Medico-Chirurgical Society, March 5th, 1902.

The pupils were unequal in size and markedly dilated; the right measured eight and the left ten millimetres; they were quite insensible to light, and only contracted very slightly on accommodation, the right pupil becoming six and the left eight millimetres in size; they did not dilate on powerful stimulation (pinching and Faradic irritation) of the skin of the neck.

There was well-marked thoracic and ulnar analgesia, and considerable analgesia and anaesthesia of the lower extremities. Biernacki's sign was not present. There was also marked analgesia of the calf muscles. There was some, but only slight, hypotonia. There was no girdle sensation. A slight dull pain in the "small of the back" was occasionally experienced. Slight difficulty in micturition (necessitating "forcing") was occasionally experienced; the bowels were regular; there was little or no loss of sexual desire and power.

There had never been diplopia or ptosis; the ocular movements and the optic discs were normal; the special senses were normal; there were no crises and no trophic or vasomotor derangements. The mental functions were unimpaired, there was no articulatory defect, and no facial or tongue tremors.

The case was interesting because of:—1. The absolute, and apparently quite straightforward, denial of syphilis and gonorrhoea. 2. The acuteness with which the ataxia had been developed; Dr. Bramwell had lately analysed 155 cases of tabes which had come under his notice, in three of these cases only was the ataxia very rapidly developed. 3. The dilated condition of the pupils. In 104 of the 155 cases of tabes which Dr. Bramwell had analysed, the size of the pupils was mentioned in the notes. In sixty-nine of those 104 cases, or 66.3 per cent., the pupils were contracted (below three millimetres); in twenty-seven cases, or 25.9 per cent. of medium size (between five and three millimetres); and in only eight, or 7.6 per cent., dilated (above five millimetres). 4. The striking and rapid improvement which had resulted from Frenkel's plan of treatment. On January 22nd the patient was unable to stand or walk, the movements of the legs being wildly ataxic. Frenkel's treatment (exercises with cross boards) was commenced on January 27th. In the course of ten days (on February 7th) the patient was able to stand and walk with the help of a go-cart. A week later (February 14th) he was able to walk with the help of two sticks. He could now (March 5th) walk steadily and well with sticks, and he could also walk across the room fairly well and without a marked ataxic gait, without sticks, i.e., totally unsupported.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

MEETING HELD WEDNESDAY, MARCH 5TH, 1902.

PETER HORROCKS, M.D., President, in the Chair.

SPECIMENS.

OVARIAN ABSCESS RUPTURED DURING LABOUR.

DR. COMYNS BERKELEY showed a uterus and appendages removed from a patient who had died twelve hours after labour had ended from acute peritonitis caused by rupture of an ovarian abscess. The patient, æt. 32, had had five children. As far as could be ascertained the only illness she had ever had was an attack of pelvic inflammation ten years previously, before her marriage. She had never complained of abdominal pain or leucorrhoea, the periods had been regular and normal. Her pregnancy was uneventful except that the morning sickness was rather more troublesome than in previous pregnancies, all of which had ended quite normally. On the evening of January 5th intermittent pains came on, between which the patient was quite well, and she considered labour had commenced. On the evening of January 7th the pain became continuous and was distressing, and about the same time the patient commenced to vomit yellow fluid. The external clerk on arrival found the pulse 100, respira-

tion and temperature normal, membranes unruptured, head presenting, cervix size of half a crown, and the patient complaining of pain and sickness. He called again three hours later, and then the patient was much worse, pulse 136, respiration 30, patient very restless, pain worse and vomiting continuing, so he sent for the Obstetric House Physician. Before this gentleman arrived the baby was born, and the patient then seemed to improve, since the pain disappeared, the vomiting ceased, the pulse fell to 80, respiration 30, temperature normal. There was no tenderness of the abdomen, and the placenta was expressed quite easily, with practically no loss. Six hours later the Obstetric House Physician was called, to find the patient very ill. Pulse 136, respiration 60, continuous vomiting, no pain, very collapsed. Dr. Berkeley was then asked to see the case. He found the stomach dilated, so that it reached to within two inches of the pubes, partially obliterated the liver dulness, and compressed the left lung, so that the percussion note over the left chest resembled that of a pneumothorax. In addition, there was marked splashing and frequent vomiting of yellow fluid without any effort. The patient was very collapsed. Dr. Berkeley diagnosed acute primary dilatation of the stomach, and asked Dr. Campbell Thomson, who lived close by, who had seen five cases, and lately read a very able paper on the subject before the Royal Medico-Chirurgical Society, to see the patient. This he was able to do immediately, and in the absence of any history or signs pointing to peritonitis agreed in the diagnosis. The stomach was emptied of over three pints of fluid and washed out, after which the patient appeared to be relieved. She, however, died six hours later. Dr. Campbell Thomson, who did the post-mortem, found purulent peritonitis with a large amount of semipurulent fluid in the abdomen. Lungs slightly cedematous. Heart, kidney, liver healthy. Spleen enlarged and soft. Right ovary healthy. Right and left tubes appeared healthy, and were pervious. Left ovary contained an opening at its lower border, through which pus was escaping, and which led to an abscess cavity. The abscess had also burst into the broad ligament, and pus was escaping from an opening in this structure. The ovary was bound down to the posterior surface of uterus by old adhesions, and he ended his report as follows: "Although the dilatation of the stomach was no doubt secondary to the peritonitis, nevertheless it formed the most prominent sign during life, and tends to confirm the view I advanced in my paper that primary acute dilatation of the stomach is closely allied to the great dilatation of the stomach and intestines sometimes found in acute peritonitis." Dr. Berkeley thought that the abscess had been burst by the contracting uterus some time between January 5th and January 7th.

The PRESIDENT said that as a student at Guy's Hospital he was taught by Dr. Hilton Fagge that there were three kinds of cases in which a woman in her ordinary health might become suddenly very ill—viz., ruptured gastric ulcer, ruptured latent typhoid ulcer, and ovarian abscess.

Dr. ROBERT BOXALL noted the absence of pain in this case, and recalled the case of a woman at University College who was doing her washing on the tenth day after labour, and was dead next day. She had no pain. She was found to have died of suppurative peritonitis. Such instances emphasised the importance of obtaining a post-mortem examination in all cases of sudden death.

Dr. HANDFIELD-JONES said that on one occasion he was asked by Dr. Danford Thomas to make an autopsy in a case of sudden death; purulent peritonitis was present, the result of a ruptured ovarian abscess; just round the ovary was a small pool of pus.

Dr. W. S. A. GRIFFITH remarked that he had seen a case of rupture of a pus-tube which rapidly led to a fatal result. It was often difficult to distinguish between an abscess of the ovary or tube antecedent to labour, and such an abscess forming part of a general infection occurring at the time of labour.

Dr. T. W. EDEN asked whether the ovarian abscess might not have been the result of bowel infection?

Dr. J. H. TARGETT suggested another explanation, namely, that the infection of the ovary might have

originated in some traumatism of the cervix, being conveyed to the ovary through the lymphatics of the broad ligament, and entering the ovary at the hilum, instead of being communicated through the tube. An attempted abortion might produce such an injury to the cervix.

Dr. COMYNS BEEKLEY replied.

INTUSSUSCEPTION WITH AN OVARIAN TUMOUR.

Dr. VICTOR BONNEY exhibited a specimen of a primary intussusception of the large intestine that was spontaneously passed by a patient, *et. 56*, who suffered from a large solid ovarian tumour which was also shown. Attached to the ovarian tumour was a large tubo-ovarian cyst. This tumour with its attached cyst was removed at the autopsy nearly five months after expulsion of the intussuscepted bowel. Dr. Bonney remarked on the rarity of primary intussusception of the large bowel and pointed out that intussusception anywhere was extremely rare after fifty, while it was still more unusual for the patient to spontaneously expel the intussusception. In this case as in two other recorded cases in patients of advanced life, prolonged constipation had preceded the intussusception.

SARCOMA OF THE OVARY.

The PRESIDENT showed two cases of malignant disease of the ovary. The patients presented several similar features; thus in both there was great distension of the abdomen by free fluid, so that tapping had to be done in the first instance. Both of them had become greatly emaciated; in each case the tumour was solid and was diagnosed as sarcoma of the ovary. Both had great pain in the side and pleurisy. The two patients recovered. The question arose in each case whether there was a secondary growth in the lung. In one case the tumour was closely adherent to the intestines, and microscopic examination showed a preponderance of pure sarcoma cells; in the other there were no adhesions, and the microscope showed that the growth was largely composed of fibrous tissue.

Dr. TARGETT remarked that the patient whose tumour was partly fibrous was forty-two years of age; the other one was twenty-eight, and it was in accordance with experience to find that the younger woman had the more malignant tumour.

Dr. CORRIE KEOP asked what was the frequency with which fluid was found in the pleural cavity in cases of solid ovarian tumours? He had seen two such cases.

Dr. AMAND ROUTH observed that when fluid was present in the pleural cavity it was generally found on the same side as the ovarian tumour.

Some observations were also made by Dr. Bonney and Dr. Tate.

Dr. W. W. H. TATE showed a small litho-pædion which had probably been in existence for sixteen years.

SUPPRESSION OF URINE AFTER LABOUR.

A paper on this subject was read by Dr. R. G. MCKERRON (Glasgow). Attention was first directed to the fact that suppression of urine before or after labour was rare, notwithstanding the frequency of pathological changes in the kidneys during pregnancy. From recent experience the author was disposed to believe that as a puerperal complication complete or partial suppression was more common than the small number of recorded cases would suggest. He described three cases which came within his own knowledge, adding short abstracts of three cases of complete anuria found in literature. The causation of anuria after labour was, he observed, obscure. To assist in the solution of the causal problem an analysis of the leading clinical features of the cases was given, from which the author concluded that several factors were concerned in its production, and that these might be variously combined in different cases. The essential causes he believed to be (1) a nephritis similar to that underlying eclampsia, and probably superimposed on kidneys previously defective, (2) a neurotic temperament (3) shock, resulting from precipitate labour or from intense pain accompanying its progress. The paper concluded with a few observations on treatment and on the possible effect of opium in contributing to the suppression.

Remarks on the paper were made by Dr. Boxall, Dr. Tate, Dr. Griffith and Dr. W. Murray Lealie, who quoted cases of anuria that they had seen. Dr. LEALIE mentioned that the subjects of the anuria were chronic alcoholics in all the three cases; that had come under his notice.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

MEETING HELD IN THE ROYAL COLLEGE OF SURGEONS ON FRIDAY, FEB. 28TH, 1902.

Mr. T. MYLES, President, in the Chair.

LIVING EXHIBITS.

MR. JOHN LENTAIGNE: Case of excision of shoulder-joint by posterior incision (Kocher) for tuberculous disease of ten years' standing.

MR. HENRY GRAY CROLY: (a) Case of medio-tarsal amputation of foot (Chopart); (b) Case of amputation of foot at ankle-joint (Syme); (c) Fracture of olecranon process treated by wiring.

CARD SPECIMEN.

MR. HENRY CROLY: Gut showing numerous ulcers (dysenteric) with perforation and gangrene.

MR. G. JAMESON JOHNSTON then read his paper on a case of

SWALLOWING OF METALLIC DENTURE SUCCESSFULLY TREATED BY THE INTERNAL ADMINISTRATION OF COTTON WOOL.

J. M., *et. 20*, whilst swimming in the open sea was struck in the face by a wave. He immediately felt a choking sensation, was unable to swim on his breast and made his way to shore by swimming on his back. Some of those on the shore slapped him on the back to displace the false teeth that he told them were choking him; the first slapping on the back produced dyspnoea. He got black in the face; a further slapping on the back got rid of the dyspnoea, though it caused him much pain. On admission to hospital a probang was passed and the patient experienced so much relief that it was felt that the denture had passed into the stomach. Soon afterwards pains in the pyloric end of the stomach were complained of, and they continued for some days. Mr. G. Jameson Johnston then decided on treating him with sandwiches containing a thin layer of cotton wool in each. A week after admission he got a drachm and a half of compound liquorice powder, which acted as an aperient, and got rid of the denture, which was found rolled in cotton wool in his faeces.

MR. LENTAIGNE confessed he would not like to take cotton wool under any circumstances. He thought it would not be without risk of producing obstruction. He considered the case important, as it impressed the well-known danger of small dentures on their notice. All the accidents resulting from artificial teeth getting into the pharynx are due to small dentures, which he thinks should be prohibited, for a large plate can be made for any case calling for artificial teeth.

MR. TOBIN would like to know if all the cotton wool the patient swallowed was passed with the denture.

MR. G. JAMESON JOHNSTON did not know either the amount of wool taken in the sandwiches or passed with the denture, the nurses having cleaned the latter before he saw it.

MR. R. H. TOBIN then read his paper on the

TREATMENT OF SENILE HYPERTROPHY OF THE PROSTATE.

Mr. Tobin traced the interdependence of the prostate gland and the testis and their correlation, and then considered the treatment of senile hypertrophy of the gland under the palliative and radical methods. In the former he placed great stress on the value of soft flexible catheters and the necessity for their asepsis. In the choice of radical methods he pointed out the value of the presence or absence of sexual desires as an indication. If these were present, the case was probably one of true hypertrophy, to be treated by vasectomy or castration; if they were absent, tumours causing pressure atrophy of the prostate probably constituted the enlargement, and

enucleation would effect a cure. The failure of vasectomy in certain cases he considered to be due to the non-inclusion, in the resection, of the filaments of the hypogastric plexus that accompany the artery of the vas deferens, these being the most direct sympathetic link between the testicle and prostate. Of the radical methods he advocates complete enucleation of the gland as practised by Mr. Freyer.

Mr. E. H. TAYLOR then read his paper on

SUPRABUBIC PROSTATECTOMY

having previously given a demonstration of the structure as well as of the normal and pathological anatomy of the prostate by means of a set of lantern slides and numerous specimens. He described the various steps of the operation and showed large adenomatous masses which he had removed. He pointed out that the aim of suprabubic prostatectomy should be: 1. To remove *en masse* and by a process of enucleation those portions of the enlarged lateral lobes which lie beside the urethra and exert a compressing influence upon it. 2. To remove the enlarged middle lobe in the same manner, seeing that its action in a large percentage of cases is to obstruct the bladder outlet. In his concluding remarks Mr. Taylor said "suprabubic prostatectomy as practised at the present day remains in its essential details, the operation of McGill and of the Leeds school, it aims at enucleation of encapsuled growths and meets all the requirements of the case. A remarkable paper appeared in the *British Medical Journal* some months ago, and another quite recently under the authorship of Mr. Freyer, of London, in which he related certain cases of *total removal of the prostate and its capsule*. Now I have no hesitation in saying, and I can prove my statements by the material which I have at my disposal this evening, that Mr. Freyer is labouring under a grave misapprehension, and has overstated his case. With his anatomy I do not purpose to enter into conflict just now. I would merely say, however, his views on the structure of the prostate bear the impress of arm chair and fireside reflection, rather than of careful study in the dissecting room and histological laboratory, in fact, one cannot for a moment regard them in a serious light. Were total extirpation carried out what would it mean? It would of necessity involve the removal of the prostatic urethra, to which there adheres in these cases a varying amount of prostatic tissue and which remains connected with the common ejaculatory ducts. These, as I have already demonstrated, are displaced downwards and backwards with their surrounding tissue, and constitute important supports of the prostatic urethra after the adenomatous masses have been enucleated. Total extirpation would also imply the detachment from its surroundings of the inter-fibrous investment of the prostate, as well as of the thinned cortex. Now, this would be not only a totally unwarranted procedure, but in the highest degree dangerous, as it would inevitably mean the laceration of the veins of the prostatic venous plexus, which lie in close contact, embedded, I might say, in this inter-fibrous layer, which Mr. Freyer alludes to as the prostatic capsule. As a matter of fact, this fibrous layer is very tough, and it is very fortunate that it is, whereas the encapsuled masses are of a much softer and more friable consistency. The result is that when the finger is introduced through the incision in the bladder floor, it finds its way, following the direction of least resistance between the tough investment of the prostate or greatly thinned cortical layer and the encapsuled mass, and this is the true explanation of the ready manner by which the enucleation of enormous tumours may be carried out. Mr. Freyer has done nothing more than remove encapsuled prostatic growths, and it appears to me that what he considers the prostatic capsule is in reality the thin fibrous investment by which these and adenomatous tumours in other regions of the body are surrounded. A glance at his illustrations alone will, I think, convince one of this fact. In conclusion, however, let me add, I am not blind to the fact that Mr. Freyer has done good work; he has, no doubt, extended the scope of McGill's opera-

tion, and in this respect I believe he has succeeded in making a decided advance in this department of surgery."

The PRESIDENT congratulated the section on the two most interesting papers they had just heard read. Mr. Taylor's was of surpassing interest. He placed his facts very clearly before them and by his caution *re* extirpation he gave them great satisfaction. The operation is not generally applicable, it is possible in a few cases only. Cases where the kidneys are diseased, and the urine purulent are not suitable for enucleation. An artificial pouch containing unhealthy urine in the immediate vicinity of the prostatic plexus is not a desirable condition. Where the urine is non-purulent and contains a normal amount of urea, and the patient is not too old nor too feeble the operation is applicable. In some of his cases he decided on suprabubic drainage. But the subject was one tempting to criticism, one on which a surgeon might talk for hours. He considered the operation much superior to perineal incision, from which he had seen a patient bleed to death.

Mr. HENRY GRAY CROLY congratulated Mr. Tobin on his practical paper and Mr. Taylor on his anatomico-surgical paper, though he thought we were not so much indebted to German anatomists for our knowledge of the anatomy of the gland, as they had really added nothing to Alcock's description. We had, however, in the treatment of prostatic hypertrophy made great progress. A patient is no longer kept for hours in suffering whilst a catheter is being passed, and now patients do not die of uræmic poisoning from an over-distended bladder, as he had once seen occur.

Mr. G. JAMESON JOHNSTON, in a case of marked hypertrophy of the prostate, which involved the whole gland and was readily recognised through the rectum, performed castration with good results. He congratulated Mr. Taylor on his splendid demonstration, which made clear it that the whole prostate could not be extirpated.

Mr. TOBIN was thankful to Mr. Freyer for having so written as to produce Mr. Taylor's excellent paper and lantern demonstration. From *a priori* reasoning it might appear that the operation was dangerous, but the good practical results showed that in spite of the reasons the operation was a valuable one. To the question, "Is the case fit for operation?" he would reply by asking, "Is the case fit to die?"

Mr. TAYLOR begged to thank the members for the kind reception of his paper. He felt sorry if he had roused Mr. Croly's indignation by not referring to Alcock's monograph, which he was aware had anticipated the German anatomists. Cases selected by him for operation are carefully fed, purged the day prior to operation, and he tries beforehand to bring their urine to the healthiest condition possible.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY. MEETING HELD MARCH 5TH.

DR. T. R. FRASER, President, in the Chair.

Dr. EDWIN BRAMWELL showed a man, æt. 38, who, after exposure to cold eighteen months ago, was suddenly seized with severe pain in the right hip. On examination a patch of anæsthesia to ordinary sensation, temperature, and pain was found on the outer side of the thigh, with a tender spot about 1½ ins. below the anterior superior spine. Otherwise the clinical examination was negative. The case corresponded with the condition described as neuralgia paræsthetica, and as the area affected coincided with the distribution of the external cutaneous nerve; and, further, as the symptoms had persisted without amelioration by other treatment for eighteen months, it was decided to excise a portion of the nerve. This was accordingly done, and while the anæsthetic area remained and a certain amount of numbness of the thigh was complained of, the patient was completely freed from pain, and was again able to resume his occupation. The excised portion of nerve showed no definite change, either by Marchi's or Weigert's method.

Mr. F. M. CAIRD showed a man, aged 68, after removal

of a portion of the small intestine for tuberculous stricture.

Dr. BYROM BRAMWELL showed (1) a man who had come under observation with symptoms of acutely developing

"TABES DORSALIS,"

full notes of which will be found in another column under the heading of "Clinical Records."

Dr. BRAMWELL also brought forward a case of consolidation of the right lung in which the diagnosis lay between aneurysm compressing the left bronchus, and a tumour. The case is of considerable interest, and for full report of which we hope to have space in our next.

The PRESIDENT, Professor T. R. FRASER, read a paper on

THE RELATIVE EFFICACY OF CACODYLATES AS THERAPEUTIC AGENTS,

An abstract of which will be found in another column under the heading of "Original Communications."

The paper was discussed by Dr. NORMAN WALKER, who was in favour of a continued trial of cacodylate of soda in certain forms of skin disease; and by Dr. RITCHIE, who stated that his experience of them had not been such as to lead him to go on using them.

Dr. NOEL PATON read a paper on the "Co-ordination of Medical Research," in which combination of several workers at one subject was advised, and suggestions were made for a further extension of the principle. The paper gave rise to considerable discussion.

Card specimens were shown as follows:—By Mr. CAIRD: (1) Cerebral tumour removed from girl; (2) Intestinal tuberculous stricture from male patient. By Mr. WALLACE: (1) Renal neoplasms removed by nephrectomy—adeno-carcinoma, sarcoma, and polycystic tumour; (2) Tuberculous intestine, fourty-four inches of which were removed by enterectomy. By Mr. MILES: (1) Spina bifida; (2) Malignant stricture of oesophagus; (3) Cases of appendicitis. By Dr. FLEMING (microscopic): Nerves ten to eighteen weeks after complete division showing regeneration of nerve fibres in the ununited peripheral portion of the nerve.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FEB. 21st, 1902.

Dr. JAMES TAYLOR in the Chair.

MR. J. JACKSON CLARKE showed a girl, *æt.* 9, who sustained a fracture of the outer condyle of the humerus in August, 1901. When seen two weeks after the injury, the elbow was rigidly extended, the ulna was dislocated backwards, and the bones of the forearm outwards. Under chloroform the elbow-joint was fixed at a right angle. There was now perfect power of pronation and supination, and an increasing degree of flexion and extension.

The case was discussed by Mr. ALFRED H. TUBBY.

Dr. C. O. HAWTHORNE showed a case of "Congenital Spastic Paraplegia" in a boy, *æt.* 2 years 9 months. There were crossed-legged progression and heightened tendon phenomena, but no positive evidences of a cerebral lesion. No specific disease or family neurosis.—Mr. CARRE-SMITH inquired as to the results of ophthalmoscopic examination.—Mr. TUBBY was of opinion that the subjects of this affection were never mentally complete.—Dr. G. A. SUTHERLAND regarded the slight strabismus present in the case as confirmatory of a cerebral origin.—Dr. ROBERT HUTCHISON was inclined to regard the case as one of Little's disease.—Dr. JAMES TAYLOR thought that syphilis undoubtedly played a part in the causation of the disease, for he had seen some patients with syphilitic choroiditis.—Dr. HAWTHORNE, in reply, said the fundus showed no changes, and that the family history was not suggestive of syphilis.

Dr. C. O. HAWTHORNE also showed a case of "Hypertrophy" affecting the right lower limb of a boy. The condition seemed to affect the bones as well as the soft

tissues. The tibial arteries had probably enlarged. Hemorrhagic spots and patches were present on the leg and dorsum of the foot. No other deformity except a moderate degree of hypospadias.—Dr. C. E. SANSONO believed this was an instance of genuine hypertrophy.—Dr. F. PARKES WEBER thought the spots and patches were distinctly naevoid. The veins and arteries of the limb were much dilated.—Dr. HAWTHORNE replied.

Mr. SYDNEY STEPHENSON showed a girl, *æt.* 11, with a "Congenital Paralysis of the Oculo-motor Nerve" on the right side. After discussing the theories of causation, he concluded that the condition was due to an absence or functional inactivity of the nuclei of origin of the nerve.—Dr. JAMES TAYLOR, after mentioning the rarity of such cases, said he did not know whether any definite lesion had yet been found in the nerve nucleus.—Mr. CARRE-SMITH asked if there was any evidence of congenital syphilis?—Mr. STEPHENSON, in reply, stated that there was neither family nor personal evidence of syphilis.

Mr. E. W. NOBLE exhibited a specimen showing perforation of a tuberculous ulcer of small intestine in a boy, *æt.* 6. The child died from general tuberculosis.—Dr. GWYNNE (Sheffield) remarked that tuberculous nodules in the intestine sometimes existed without causing any symptoms. He had come across such nodules when operating for the radical cure of hernia in children.

Dr. W. C. CHAFFRY (Brighton) exhibited a specimen of Cirrhosis of the Liver from a girl, *æt.* 10.—Dr. LISTER thought that some obscure cases of cirrhosis of the liver in children might be explained as the result of an acute enteritis.—The CHAIRMAN alluded to a case in a girl, *æt.* 15, who suffered from choreiform movements.—Dr. WEBER and Dr. SANSONO also discussed the specimen.

Dr. GEORGE CARPENTER showed a case of Paroxysmal Hemoglobinuria in a boy, *æt.* 3. There was no evidence of syphilis. Application of ice-cold water to the extremities induced an immediate destructive action on the red corpuscles to the extent of 20 per cent., but failed to produce hemoglobinuria.—Dr. WEBER urged the importance of a warm climate in the management of such cases.—Dr. Hawthorne, Dr. James Taylor, and Dr. Sutherland discussed the case, and Dr. CARPENTER replied.

Dr. CARPENTER showed a case of Extreme Ichthyosis in a male infant, aged 5 months, which developed a few days after birth. It also had craniotabes and chronic snuffles. Dr. Carpenter also showed a boy, *æt.* 8½, with a large head, probably hydrocephalic, a supposed sequel of basilar meningitis during infancy. There was rigidity of the lower extremities and a feeble gait. The enlarged head was not characteristic of hydrocephalus, and it was somewhat suggestive of hypertrophy of the brain.

Dr. C. N. GWYNNE (Sheffield) described the case of a boy, *æt.* 6½, who was admitted to hospital suffering from obstinate constipation and great emaciation. His abdomen was enormously enlarged. As no action of the bowels could be obtained, either by medicine or by injection, left iliac colotomy was performed. The condition was diagnosed as a congenital dilatation of the sigmoid flexure of the colon. The result of the operation was satisfactory.

Dr. J. PORTER PARKINSON read a paper on the

LOCAL TREATMENT OF ADENOIDS.

This consists in the direct application to the nasopharynx of an astringent compound of equal parts of solution of perchloride of iron and glycerine, applied by means of a curved brush passed behind the soft palate. Dr. Parkinson advises this treatment for soft and gelatinous adenoids, which cause temporary, recurrent obstruction of the nasal passages and other symptoms, as cough, headache, aurial discharges, and deafness. The method is applicable to patients of any age, and can be carried out with a minimum of discomfort.—Dr. G. A. SUTHERLAND discussed the paper, and Dr. PARKINSON replied.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD FEB. 27TH, 1902.

RUSHTON PARKER, M.B., F.R.C.S., President, in the Chair.

Dr. THURSTON HOLLAND read a note on the
DURATION OF PREGNANCY,

based on a case—that of a young primipara—when, dating from the last date of normal menstruation to the birth of the child, the duration was 340 days, from the date of last coitus to the birth was 323 days, from the date of the menstruation following the last coitus (an abnormal period only lasting two days) the duration was 316 days.

Dr. MACFIE CAMPBELL said he had notes of sixty-four cases in which the date of impregnation was known, and the average came to 268 days, or rather less than is generally allowed. In one case of seduction 273 days elapsed after one coitus. Nine cases of no menstruation after marriage gave an average of 264 days, and in five when the husbands (seafaring men) were only at home for one night, 277 days. He never had a case similar to that of Dr. Holland, which was open to a little doubt; it was so difficult to be quite sure of our data in these matters. He had, however, notes of six cases ranging from 293 to 303 days, three of 308 days, one of 310 days, and one of 312. Dr. Holland's paper was of much interest from a professional and legal point of view, and showed how important such a question might be.

Dr. R. T. M. BUCHANAN and Mr. R. A. BICKERSTETH read the notes of a case of Gastric Ulcer, in which a successful operation had been performed for perforation. J. C., a housemaid, *et.* 27, had a history of epigastric pain and occasional vomiting for two years. Twenty-seven hours after the symptoms of perforation came on laparotomy was performed at the Royal Infirmary. Much turbid fluid was found in the abdomen, collected in pockets formed by recent adhesions. A perforation near the cardiac end of the stomach was found with some difficulty, and eventually closed by passing a rectangular cleft palate needle deeply through the tissues on each side of it. The operation was performed on August 6th, 1901; the girl left the hospital on October 20th, and continued well up to the present.

Dr. W. BLAIR BELL related a

CASE OF APPENDICITIS

which had run an unusual course. At the operation he found an empty abscess cavity. The stump of the appendix was ligatured and removed from the cæcum, and the apex from the ileum to which it adhered, and where there was a large perforation through which the abscess had discharged into the bowel. He closed the perforation, and packed the abscess cavity with gauze, soaked in iodoform emulsion. The patient, a girl, *et.* 16, made an uninterrupted recovery.

Mr. LARKIN read a case of

CEREBRO-SPINAL RHINORRHOEA.

The fluid had escaped through a fracture of the basiphænid. The patient lived twenty-seven days after the fracture, and died from septic meningitis.

Drs. Macalister and E. T. Davies, Messrs. F. T. Paul and G. P. Newbolt and the President discussed these cases.

Dr. NATHAN RAW read a paper on

THE RELATION OF MENTAL SYMPTOMS TO BODILY DISEASE.

He first of all minutely described the symptoms present in various diseases of the viscera, with special reference to reflected visceral pains, and agreed in the main with the conclusions of Head, that they were present in a fair proportion of cases of heart disease, phthisis, and diseases of the stomach and liver. He then described the various mental symptoms occurring in the course of kidney disease, gout, exophthalmic goitre, myxœdema and chorea, mentioning several cases of temporary insanity which he had noticed. The mental symptoms occurring in the course of typhoid, pneumonia and rheumatic fever he divided into two import-

ant groups, those of the initial stage of the fever due to the severity of the infection and characterised by mania and delirium, and those supervening on convalescence, chiefly of a depressant and melancholic type. He had often observed post-typhoid insanity of the melancholic type with delusions, and was of the opinion that it was due to nervous exhaustion and insufficient food. In his experience post-typhoid insanity always passed off, and the patient's mind was restored to the normal. He had never observed insanity to follow an attack of pneumonia. After a long observation of many thousands of cases, Dr. Raw was of opinion that there was a form of temporary mental disorder which occurred as part and parcel of some bodily diseases, and which rendered the patient insane for the time, but which rapidly passed away. He was strongly of opinion that those cases should not be certified as lunatics and sent to an asylum, but should be treated in a special hospital for mental diseases. He advocated the provision of a reception house or hospital for mental disorders in Liverpool, where a patient suffering from delirium tremens and other forms of temporary mental disorder could be sent and specially treated, and facilities given to students for studying this important group of mental disorders, and he was of opinion that such patients should not be subject to the stigma of having been certified as lunatics when a few weeks of special care would restore the mental equilibrium.

Dr. WARRINGTON mentioned the important observations of Sherrington, who found that the emotional life of dogs seemed to be unimpaired after a complete section of the spinal cord below the origin of the phrenics, and also in addition, section of one vagus nerve. He also alluded to the fact that innumerable poisons which could be demonstrated in the nerve cells, and expressed the opinion that these changes had no distinguishing features from one another. He considered the characteristics of mental disorder in visceral lesions depended rather upon the psychological life of the individual.

Drs. T. E. Glynn, Carter, Gill, Street, and Barr spoke, and Dr. Raw replied.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT LIVERPOOL, FRIDAY, FEB. 21ST, 1902.

S. BUCKLEY, M.D., President, in the Chair.

Dr. T. ARTHUR HELME (Manchester) showed:—

1. Carcinoma of the cervix uteri with double pyosalpinx, removed per vaginam from a nullipara, *et.* 23. The patient had been married about twelve months. The husband had had gonorrhœa a few months before marriage. The symptoms of menorrhagia and discharge had existed about six months. The points of interest in the case were the early age for cancer, its occurrence in a nullipara, and the association with gonorrhœal pyosalpinx. The growth consisted of columnar carcinoma.

2. Polypoid carcinoma of the corpus uteri removed by vaginal hysterectomy from a virgin, *et.* 41. The operation was rendered difficult by the smallness of the vagina and incision of the perineum was required, and also median incision of the uterine wall. The ligaments were clamped. The growth was gland-celled carcinoma. It originated in the right side of the uterine body forming a large polypoid mass protruding into the vagina.

3. Solid ovarian tumour and primary (?) tuberculous peritonitis with ascites. The patient had for some months previous to operation been losing flesh and noticed the abdomen to become gradually enlarged. There was an evening rise of temperature which was subnormal in the morning. The physical signs were those of considerable free fluid in the peritoneal cavity, together with the presence of a solid oval tumour in the right ovarian region. The uterus was not enlarged. The history, general condition and physical signs suggested tuberculous peritonitis rather than simple ascites associated with the tumour. The abdomen was opened and the tumour removed. It was a fibroma of the right

ovary. There was no evidence of malignancy. The whole of the posterior surface of the right broad ligament and uterus were covered with a thick caseous tuberculous-looking material, and the pelvic peritoneum generally showed the usual evidences of tuberculous peritonitis. Both Fallopian tubes appeared healthy. The ascitic fluid was removed and the abdomen closed. The patient has completely recovered health at the present date, nine months after operation.

The specimens were discussed by Dr. E. T. Davies and others.

Dr. LLOYD ROBERTS (Manchester) showed a large uterine polypus removed from a married woman, *æt.* 52. There was commencing necrosis with offensive discharge and bleeding. The pedicle about twice the thickness of a thumb sprang from the posterior uterine wall above the internal os. In addition to the polypus, the posterior conical lip and adjoining vaginal fornix showed superficial ulceration. The appearance of the polypus suggested the possibility of malignancy, but examination failed to reveal this condition. A further investigation would be made.

Dr. W. WALTER (Manchester) showed a solid tumour of the right ovary, removed by abdominal section from a multipara, *æt.* 39, whose periods suddenly ceased five years previously. The other ovary was small and atrophied, and no ascites was present. At the outer end of the tumour, which was the size of a small cocoon, the capsule was very thin and friable, and over a small area the contents were pink and of a putty consistence. The remainder of the tumour was firm and cut like a pear. Some parts looked like a fibroma, but microscopically the ovarian stroma was found extensively infiltrated with round-celled sarcoma.

Dr. Briggs, Dr. Donald, and the President, Dr. Buckley, discussed the difficulty of distinguishing benign from malignant connective tissue tumours of the ovary, and Dr. WALTER replied.

Drs. A. DONALD and W. K. WALLS (Manchester) related a case of spontaneous rupture of a uterus, *biicornis unicollis*, during pregnancy. The first four confinements had been tedious or instrumental. The fifth labour occurred in St. Mary's Hospital, and is described by Dr. Walls in the Society's "Transactions," 1899. The present labour commenced with pain and hæmorrhage, and the placental edge was felt first within the cervix. The cervix was plugged, but as bleeding recurred and pains did not continue, a leg was brought down, under chloroform. The skin of the fœtus was peeling. Multiple incisions were made in the cervix, and the base of the skull perforated. The cervix was lacerated, the tear involving the broad ligament into the peritoneal cavity. On passing the hand into the uterus to remove the placenta the two horns of the uterus were found to have separated, the intervening thin tissue having given way. The abdomen was opened, and pan-hysterectomy done. The patient made a good recovery.

Dr. H. BRIGGS (Liverpool) exhibited:—(a, b, c) Three examples of solid ovarian carcinomata; (d) Necrobiosis of fibroma of the ovary; (e) Double ovarian cystoma and pregnancy; (f) Vaginal nodules in case of adenocarcinoma of the cervix.

Remarks were made by Drs. Donald, Lloyd Roberts, Walter, Raw and Helme, and Dr. BRIGGS replied.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, March 9th, 1902.

THE NEW THERAPEUTIC, ARRHENAL.

In a communication recently made to the Académie de Médecine Professor Gautier brought under notice arrhénal, a new chemical, which he considers will be a valuable therapeutic remedy in the treatment of pernicious anæmia and pulmonary tuberculosis. It is, as its chemical formula shows, a disodium methyl arseniate, which chemically is allied to arsenic dimethyl, or

cacodyl, $\text{As}(\text{C}_2\text{H}_5)_2$, which Bunsen obtained from cacodyl chloride. The series is interesting from an historical point of view, for the first organo-metallic-basyl was yielded by them (AsC_2H_5).

In the present instance Professor Gautier has succeeded in displacing the organic radicle, C_2H_5 , by sodium, and the substitution of the one radicle for the other has given a practically non-toxic agent for a lethal one.

Physicians for the past two or three years have been prescribing arsenic in the form of the now well-known salt, the cacodylate of sodium. But those who have experience of the salt know how unpleasant to the patient is the garlic-like odour it imparts to the patient's breath, and the offensive smell it so often gives to his sweat. No matter how given, hypodermically, by enemata, or by mouth, the unpleasant effects follow.

With arrhénal there are none of these undesirable results, withal the therapeutic action of the cacodylate remains unimpaired. The drug has been used in many cases by its discoverer, who recommends that it be administered hypodermically in doses of from five to ten centigrammes. In malarial cases he found it more active and much more trustworthy than quinine, two or three hypodermic doses being sufficient to effect a cure. Under the influence of the drug the red corpuscular elements of the blood increase enormously, a few doses bringing the red blood-cells from 3,844,000 to 5,022,000. M. Gautier does not hesitate to double the dose usually given, when the effects of the medication are not found to follow its administration.

The effects of the drug in phthisis are so marked that it needs the greatest faith in our French professional brethren to believe the report, though it is such as we desire. Under the influence of arrhénal, the cough diminishes in frequency and intensity; the pains in the stomach and vomiting cease, and the appetite returns. These wonderfully good effects are stated to be wholly due to the action of the drug. Its good effects are not confined to the lungs, it acts beneficially on the liver and kidneys. These statements are confirmed by Alb. Robin, who has been tentatively using the drug in phthisis and renal diseases.

In phthisis the drug is given twice daily during meals, ten drops of a five per cent. solution being used. When the drug has been taken for seven days the patient is recommended to discontinue its use for seven days, during which time a syrup of some tannate may be prescribed, syrup of walnuts being a favourite. But all its virtues are not exhausted, for it is credited with stopping the worming sickness of pregnancy. Withal it must be borne in mind that the therapeutic properties of the salt are stated from the actual clinical experience of one of the most distinguished French chemists and all such as might fairly be deduced from the chemical formula of arrhénal.

Further, Professor Gautier placed his formula and the results of his experiments fully before his professional brethren, and solicited them to further test the value of the salt from which he hoped so much.

The preparation is worthy of a tentative trial, and in so using it there is practically no risk of any untoward result, for the toxic dose is much greater than the maximum medicinal amount for the day.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 8th, 1902.

At the Dermatological Society Hr. Heller showed a patient, æt. 24, who in connection with an attack of gonorrhœa was suffering from gonorrhœal disease of the shoulder and

GONORRHOËAL MYOSITIS.

The patient had acquired syphilis two years before, and in July, 1901, gonorrhœa. By coitus before complete recovery he had had two relapses or super-infections, and in January there was again a gonorrhœal urethritis, both anterior and posterior, with acute prostatitis. About the middle of the month there was slight gonorrhœal disease of the left shoulder. There was great pain, especially at night; general feeling of malaise, but no fever. Salicyl was of no use, but treatment by ichthyol externally and potassic iodide internally, with rest, succeeded moderately. A week later a large stony-hard infiltration was felt in the left biceps which increased in size during the next two days. Its form corresponded generally to that of the biceps. Electrical examination gave normal effects. There was no evidence of nerve disease, and no muscular contraction could be set up. Five cases of gonorrhœal myositis, he observed, had been recorded. In one case an incision was made under the impression that the swelling was an abscess. Both in the muscle and in the intra-muscular exudation, undoubted gonococci were found. In the case shown potassic iodide brought about a rapid improvement.

Hr. Ledermann showed a microscopical preparation illustrating a case in which

POST-GONORRHOËAL URETHRITIS WAS SET UP BY BACTERIUM COLI.

A gentleman, æt. 40, had had his urethra treated both externally and internally on account of numerous complications. Complete recovery having taken place in April, 1901, he came back in November complaining of discharge from the urethra. Examination showed a few pus corpuscles, and many long chains of bacterium coli. A pure cultivation was readily made. The speaker was of opinion that the *b. coli* reached the urethra through the lymph channels. As no instrument was introduced into the urethra, infection from without was excluded. Recovery soon took place under urotropin and a few injections of permanganate.

The *D. Archiv. f. Kl. Med.*, 62, 5 and 6, contains an article by Hr. Herm. Heincke on the

CAUSE OF DEATH IN PERFORATIVE PERITONITIS.

By causing perforations in rabbits death generally took place in from six to twelve hours, the investigation after death leading to the following conclusions:—That the cause of death was a paralysis of the centres in the medulla oblongata; in the first place, the vaso-motor centres were affected, and in the second, those of respiration, the circulation showing striking disturbance before respiration became affected. The heart was unaffected so far as the vaso-motor disturbance was concerned. The circulatory disturbance ran a course exactly analogous to that of infectious diseases. The paralysis of the nerve centres was the consequence of the passage of bacteria products from the peritoneum into the blood.

At the Medical Society a discussion took place on Hr. Kamnier's paper on

TOXINÆMIA.

Hr. Lazarus had examined the blood in a large number of cases of infectious disease with regard to the affinity for iodine. The iodine reaction of the leucocytes was often present, although not constantly, in hyperleucocytosis. He found the reaction in croupous pneumonia, endocarditis septica, acute pericarditis, tonsillar abscess, scarlatina, erysipelas, various carcinomata, lysol poisoning with pneumonia, arthritis gonorrhœica empyema, febrile phthisis, acute enteritis, and tuberculin reaction, but not in anæmia, sarcomatosis, cancer of the liver, typhoid, and diabetes. He attributed it as did Ehrlich, to the glycogen constituent of the blood. Gabrilischewsky obtained it by experimental glycosuria Czerny by morphia narcoosis, section of the vagus, blood letting, and by setting up aseptic suppurations. As it was to be met with under such a large number of conditions, its presence was of no decisive diagnostic value. The speaker had found the condition intermittent, and inconstant in two cases, one a case of osteomyelitis ten days after delivery, the second one of septic endocarditis.

Hr. L. Michaelis looked upon iodophile leucocytes as degenerated, not as dead. He, like Kamnier, had never found them in abscesses not of bacterial origin.

Hr. Lazarus looked upon the iodine reaction as one not of degeneration, but of regeneration.

At the Free Society of Surgeons Hr. Neumann showed a patient the subject of

SUBCUTANEOUS RUPTURE OF INTESTINE AFTER CONTUSION.

The man fell from a scaffolding on to the edge of a mason's hod. He was taken into the Friedrichshain Hospital at once. On admission there was a good deal of collapse, with vomiting, the abdomen drawn in, excessively tender; in both hypochondria dullness, which continued after the withdrawal of clear urine from the bladder. Six hours later laparotomy was performed. In the abdominal cavity was a brownish fluid free from odour. The loops of intestine were covered with fibrin. Liver and spleen were intact. The intestines were now taken out and washed with large quantities of saline solution, and then replaced until a perforated spot was reached. This was resected for a distance of 10 c.m., and union being made by Murphy's button. The abdominal wound was only partially closed. For the first two days symptoms of diffuse purulent peritonitis were present, then improvement set in, and the patient was discharged well in five weeks.

During the past twenty years there had been 133 cases of abdominal contusion in the hospital; 71 uncomplicated, 63 with tearing of abdominal organs. Of all symptoms there was no one absolutely proof of intestinal rupture. Severe shock was generally present, but occasionally it might be absent, and in an uncomplicated case it might be present; the same of muscular tension. One could be completely led astray by giving opium; it should therefore not be given at all.

Twenty-one cases were operated on, of which one only—the one shown—recovered. All the cases before operation showed grave symptoms; the abdomen contained faeces, all the coats of the intestines being torn through,

and all were hard to persuade to submit to operation. If anything was to be done, however, early operation was necessary, and especially if the impact on the abdominal wall has been limited to a small area.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 8th, 1902.

THE TUBERCULOSIS COMMISSION.

At the opening of the "Gesellschaft der Aerzte" Prof. Chrobak explained that since the last meeting of the Society seventeen members had formed themselves into a special committee to investigate the question of tuberculosis to a final issue. This, he thought, would be gratifying to all the members who had followed the recent developments of the subject.

PROPHYLAXIS OF TUBERCULOSIS.

Holzknacht resumed the discussion on Weichselbaum's paper, which has given rise to a wide diversity of opinion on the origin, prophylaxis, and treatment of tuberculosis. Holzknacht commenced with a reference to Kaiser's experiments, which he thought were of the utmost importance in the treatment of the disease. He was personally very sceptical as to the efficacy of the blue rays acting so deeply when the surface showed so little change under such influence.

He pointed out that there was no previous evidence of either the Röntgen or Becquerel rays with any sort of coloured light having a deep internal action, the power of penetration being so great that the rays were assumed to pass through the object without affecting it; on the other hand, if the rays become absorbed the superficial plane of entrance must be proportionally more markedly affected; the deeper rays having diminished in potency in proportion to the depth. It had been frequently demonstrated that the blue and ultra-violet blue rays are rapidly absorbed by the skin, which would greatly weaken the effect of rays penetrating the morbid structure, and a ray that would reach that structure would destroy the cutaneous surface. He concluded that Kaiser's method of treatment was a bad form of sunshine, and therefore worthless. His success could only be due to the free use of tropon and not to the rays.

Kronfeld challenged Winternitz's assertion that "the power of tuberculous infection is very low." He believed with Cornet that the disposition was a powerful factor, but the disease was also very easily transmitted. He would not dogmatise on the subject, and hoped this would give the whole subject new interest. He thought the treatment in distinct institutions at the cost of the State would be premature with our present imperfect knowledge. It was not even yet decided whether such institutions were beneficial or prejudicial to the health of the patients, as so many conditions must be observed, which almost excluded a beneficial result in any other cases than those which would have improved under any other form of rational and hygienic treatment. We have an abundance of evidence to prove that such institutions are in some cases positively injurious. A patient may be suffering from a slight form of the disease for months, or even years, when persuaded to enter one of these institutions to be "perfectly cured." He returned to his modest home with the laudable con-

viction of having performed his duty when, contrary to our hopes, the disease took on an acute aspect, and soon killed him, leaving his friends to regret that he ever left his home to undergo "the cure"! The sputum, he believed, was best collected in spittoons made of asbestos and cement. This combination facilitated washing with strong disinfectants and exposure to heat.

Freund said he could not see any advantage in excluding the red and yellow rays, as was affirmed by Kaiser in his treatment. In his own practice he found these red and yellow rays heal the stubborn ulcers more quickly than the blue rays, which tended to place Kaiser's method in the category of irrational treatment.

Winternitz reiterated his argument that the origin of tuberculosis depended more on predisposition than on direct infection. As a proof of this he adduced the evidence afforded by the attendants for the dead, who washed bodies and handled them freely with impunity unless their health was reduced, which opened the door for infection.

Moreover, a fact confirmed by many observers was that in half the bodies examined after death tuberculous lesions were found, though no clinical symptom or data were observed during life. He asked how any isolation or disinfecting method could be instituted to stamp out bacilli, the presence of which was unknown. They are cast about broadcast during life, only to be discovered after death. No retreat or institution could have the slightest influence over the dissemination of such masses of tubercle. He said he could only repeat the view that by increasing the resistance, by improving the homes, erecting healthy public kitchens and baths for the people they could alone hope to stamp out the disease by enhanced resistance, whereas isolation, as in homes or institutions, would be quite inoperative.

The Operating Theatres.

GUY'S HOSPITAL.

UNFORTUNATE SEQUEL TO A CASE OF WIRED PATELLA.—Mr. ARBUTHNOT LANE operated some time ago on a man, æt. 45, for fracture of the left patella, the right having also been previously wired for fracture. The man was an alcoholic subject, and seemed to be constantly in the wards. In the operation the wire did not enter the joint but passed through the patella two lines in front of its cartilaginous surface. The knot in the wire was carefully hammered down so as to form no prominence beneath the skin. About six months afterwards the man sustained several injuries and struck the front of his patella, cutting the skin over the wire. He paid no attention to this, although the wire appeared in the wound and a certain amount of discharge came away. At the end of three weeks the knee became suddenly painful and swollen, and in two or three days the patient became seriously ill. He was admitted into the hospital with an ulcer on the skin over the patella, in the floor of which the silver wire and knot were visible. The joint and the parts about were acutely inflamed and very much swollen, and when pressure was made upon it, serum and pus oozed out along the track of the wire. The joint was freely opened, the patella being cut through transversely. It was then seen that an abscess had formed along the track of the wire.

and that this communicated with the interior of the joint by means of a small aperture in the articular bony lamella and cartilage of the patella; the infection was clearly a very virulent one, and the joint was very acutely inflamed, the soft parts being much disorganised. It was decided to make an attempt to obtain a stiff knee-joint in the extended position. The joint was thoroughly washed out and packed with sulphur. This case, Mr. Lane said, was of very considerable importance, since it showed the risks involved in the presence of a wire in the vicinity of a joint in a very careless or intemperate subject, therefore in such a case the surgeon would be well advised to remove the wire after it had effected its purpose.

After a considerable interval the inflammatory process subsided. Unfortunately the head of the tibia became displaced backwards sufficiently to prevent the patient's using the leg as a secure support; it was then determined to excise the knee-joint, and the man has been re-admitted for that purpose.

NEPHRORHAPHY.—The same surgeon operated on a woman, set. 35, for extreme mobility of the right kidney which produced three distinct sets of symptoms:—(1) Attacks of jaundice; (2) attacks of urinary obstruction in its pelvis; (3) very considerable enlargement and swelling with much pain. The last symptoms always developed after she had been some time in the erect position, and bore a direct relation to its duration. When she was tired out, as she usually was at the end of the day, the dragging pain and the tenderness in the iliac fossa were very great. The kidney was fixed in position by means of triangular flaps of capsule by a method which Mr. Lane described in the "Transactions" of the Clinical Society, "A Case of Floating Kidney Treated by a New Mode of Nephrorrhaphy." The method employed was as follows:—The kidney was thoroughly exposed through a slightly oblique incision in the loin and freed from the fat that was present. As it projected from the wound the capsule was stripped from its lower two thirds in the form of six triangles, the bases of the triangles being left intact. In order to increase its resisting capacity each was twisted up, when a piece of sterile silk was tied securely to it. The kidney was then replaced within the abdomen in such a position that little more than half of it was exposed below the rib. Needles were then placed on each silk thread, and were passed through the muscles within an inch of their cut margins, so as to bring the raw surface of the kidney into apposition with the deep surface of the muscle wall freed from fat and fascia. The incisions in the muscle wall and skin were then brought accurately together. Mr. Lane pointed out that when these sutures have been secured the resistance offered by the capsule is so considerable that it would require the expenditure of a great amount of force to displace the kidney from the position in which it had been fixed. He said that he had

Fig. 1.—Posterior surface of kidney. The dotted lines are the triangular areas, 1, 2, 3, 4, 5, and 6, from which the segments of the capsule, 8, 9, 10, 11, and 12, have been stripped.

Fig. 2.—Conditions after incision, C D, through muscular wall has been closed. A B shows the margin of the chole

performed this operation a very large number of times, but he had never known the kidney to move from its attachment to the wall; he further remarked that on two occasions he had subsequently to expose such a kidney to remove a stone and that he had observed that the kidney substance and muscle wall were most intimately united. Mr. Lane was strongly of opinion that the operation of excision of the kidney was undertaken much too frequently and often unnecessarily. He thought that surgeons should not resort to such a serious measure till every other means has been tried to save the organ, following the same general principles that guide us in operations on the limbs.

REGISTERED FOR TRANSMISSION ABROAD.

The Medical Press and Circular.

Published every Wednesday morning, Price 5d. Post free, 5½d.

ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5 0s. 0d. Half Page £2 10s. 0d., Quarter Page, £1 5s.; One-eighth, 12s. 6d.

Considerable reductions from the foregoing scale are made when an order is given for a series of insertions. Terms on application to the publisher.

SUBSCRIPTIONS.

Subscriptions may commence at any period of the year. If paid in advance the cost is only 21s. per annum, post free. An edition is printed on thin plate paper for foreign and colonial subscribers at 21s. per annum, post free, if paid in advance, or 23s. 6d. credit rate.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under, 4s. per insertion; 6d. per line beyond.

WEDNESDAY, MARCH 12, 1902.

POOR-LAW NURSING.

THE recent appointment of a Special Commission to investigate the conditions of Poor-Law nursing in the United Kingdom will be hailed with satisfaction in many quarters. The fact of its being called into existence may in itself be regarded as a recognition of the imperfections of the present system. Speaking broadly, there can be little question that the general standard of Poor-Law nursing has not advanced in equal ratio with that of ordinary life. The explanation of that fact may probably lie in a variety of causes, some of which are not difficult to realise. At the present day, sick nursing is a skilled pursuit, calling for the possession of some amount of special aptitude, and for a somewhat prolonged course of training. In our general and special voluntary hospitals, as everyone knows, the standard of nursing has enormously developed and improved within the last two generations. The nurse is no longer an ignorant drudge, taken haphazard from the lower classes of society and pitch-

forked into the responsible duties of a ward nurse, but at the present moment she is for the most part a skilled, educated and capable woman. There is still room, however, for a considerable leaven of the best modern type of nurse in the Poor-Law infirmaries of the United Kingdom. Indeed, in some cases, judging from reports of special inquiries that have appeared in certain medical journals and from scandals that have arisen from time to time it may be inferred that in some of the smaller urban and rural Poor-Law infirmaries the system of nursing is absolutely unworthy of modern humanity and enlightenment. One of the chief abuses is the employment of pauper inmates as attendants on the sick. It may be doubted whether the public have any adequate idea of the wide prevalence of this utterly indefensible system. In some of the small country infirmaries it is the rule rather than the exception, especially as regards imbecile and bed-ridden patients. The Commissioners in the present inquiry will, no doubt, furnish figures showing the extent to which paupers are employed as nurses in Poor-Law institutions. The key to the employment of unskilled services of the kind is clearly the desire of the Guardians to cut down administrative expenses. A similar parsimony lies at the root of another great flaw in the present Poor-Law nursing system, namely, that of understaffing. The hours of work exacted from the nurses are often excessive, and the number of patients allotted to each nurse far in excess of any reasonable standard. The results are bad from every point of view: the interests of the patients and the health of the nurse are sacrificed at the shrine of false economy. We have reason to believe that not a few untoward accidents happen to inmates in Poor-Law institutions arising from an insufficient staff of nurses. In many cases these occurrences are hushed up, and are not always disclosed even when a coroner's inquest is called upon to make an investigation. One of the most common causes of risk consists in placing a single nurse in charge of three, four, or even six wards containing perhaps a number of acute cases. In some modern Poor-Law infirmaries these wards are in separate blocks, and it is evident that there must at times be great danger in the case of delirious or otherwise unruly patients. Even the best of the provincial hospitals fail in the adequacy of the nursing staff in numbers, and it is to be hoped that this point will receive the fullest attention from the Commissioners. A fixed and definite ratio of nurses to patients, both by day and by night, should be fixed by the Local Government Board and imposed upon local authorities. It would be a mistake to suppose that bad Poor-Law nursing is to be met with only in the provinces. The Poor-Law infirmary system of London demands a thorough investigation on all points, and nowhere more than on that of nursing. Some of the revelations with regard to the prevalence of pauper attendants and to the inadequate nature of the nursing staffs, both as regards training and

numbers, would, we believe, afford a certain amount of sensational matter. There are one or two such institutions the padded rooms of which for years past, if we mistake not, have afforded material enough for a series of scandals. The present Commission is well adapted for its purpose, and the resulting report may be awaited with confidence. It is to be hoped that on the conclusion of its labours speedy action will be taken by the Local Government Board, or, if necessary, by Parliament itself.

LAWYERS AND MEDICAL MEN.

NOTHING in legal procedure is so perplexing to the non-legal layman as the license which counsel allow themselves in the language they use towards witnesses. It is apparently a common practice for counsel to accuse a witness of acting disgracefully, of perjuring himself, and of being altogether a disgrace to whatever surroundings he may possess, because the said witness does not give evidence in support of the examining counsel's client, and then on the following day to apologise for his "Chancery invective." Such a procedure may possibly be defensible in jury cases, where the abuse of the opposing counsel, his client, and his witnesses, is the common line of defence in an undefendable case. But where such practices are carried on before a tribunal composed entirely of judges, on whose minds the irresponsible statements of lawyers have no effect, it is impossible to defend them. They cannot help the client of the denunciatory lawyer, and they are bound to have some slight effect on the public mind. Of ten men who read the gross insults which are heaped on the head of a witness, perhaps six read the subsequent apologies. The result of such a state of affairs is prejudicial to the interests of the public, inasmuch as it directly tends to keep out of the witness-box such witnesses as would enter it of their own accord to help the ends of justice, and who being entirely unprejudiced are most valuable. Lawyers would doubtless deny the existence of such witnesses. They do well to do so, for they have killed them. During the hearing of a recent action at law, in the case of a disputed will, before the Master of the Rolls—a case in which the children of a money-lender were fighting for the possession of her money—a former President of the Royal College of Physicians of Ireland was called upon to give evidence regarding the state of mind of the testator, who had been a patient of his. He gave his evidence in the most irreproachable manner, and in its course mentioned that solicitors from all parties had come to ask for his evidence beforehand, but that he had put them off by saying that he would give it in Court. The next day Mr. Ronan, counsel for the claimant whom the medical evidence had not favoured, said in the course of his speech "that the medical witness had charged one solicitor two guineas for putting him off; what did he expect from the other side for putting them on? A more disgraceful performance on

the part of a respectable man in his profession," &c. Subsequently a settlement was arrived at, and the Solicitor-General, speaking in Mr. Ronan's absence, apologised for Mr. Ronan's remarks, saying that they were to be attributed to his powers of Chancery invective, that the medical witness had behaved with the strictest professional propriety, and that his standing and position were the highest in Dublin. This is all very well as an apology, but what is it an apology for? Is it an apology made on behalf of an eminent King's Counsel because he cannot restrain himself from using Chancery invective before the Master of Rolls, and that too in spite of the fact that he had already been pulled up by his Lordship for a similar display of his powers towards a brother King's Counsel? Or, is it a *bona-fide* apology for an unwilling discharge of an unpleasant professional duty? There is very little doubt as to which is the correct explanation. The necessity for using Chancery invective regarding witnesses before the Master of the Rolls, is as great as the necessity for throwing a more material form of mud at them. Consequently, there is no room for a plea of necessity. Whatever may have been Mr. Ronan's motive we commend the observation of the Master of the Rolls to his attention. "With regard to the remarks of the Attorney-General on the conduct of the medical witness, I desire to express my entire concurrence, and to say that if the case had run its long course, I would have considered it my duty, whatever became of it, to express an exactly similar opinion."

THE TREATMENT OF INCIPIENT INSANITY.

THE proposal discussed at a recent special meeting of the Edinburgh Medico-Chirurgical Society, and reported in our last issue, to establish wards in the Royal Infirmary for the treatment of incipient and transient cases of mental aberration, is one which will meet with general approval, and will also provide a golden opportunity for some rich benevolent benefactor to confer a boon on his poorer and more unfortunate brethren by coming forward with an endowment. The subject has been made conspicuous by Dr. John MacPherson, Commissioner in Lunacy, and Sir John Sibbald, who formerly held a similar appointment, and the audience comprised many eminent asylum medical superintendents, among whom were Sir John Batty Tuke, Dr. T. S. Clouston, and Dr. A. R. Urquhart. In Scotland the general opinion seems to be that it is desirable to have accommodation for treating this special class of case in the Royal Infirmary; mental derangement is curable, and, indeed, the majority of cases prove this if they are treated properly and with alacrity. But the law and the irregularity of the disease hinder prompt treatment. Asylums are not merely places of refuge for the insane, but, unfortunately, their curative propensities, as a rule, are only brought to bear upon cases in an advanced stage. The early stages of mental disorder are almost entirely

neglected, and many patients are allowed to fall into an incurable condition, when such a miserable fate might have been averted. The great importance of early treatment in all cases of insanity has never been fully realised, and the public delay too long in committing their friends to the care of a mental hospital, and shrink from the clinging stigma attached to a person who has been unfortunate enough to require the treatment meted out by such an institution—a strong argument of itself in favour of a Psychiatric Clinic. Or it may be, that a man belonging to the poorer class of the community suffers from incipient disease, his friends are unable to provide the treatment necessary, and have consequently to wait till the disease reaches the stage when he can be certified as insane. Recovery in both instances is now almost hopeless, and the probable result is that they spend the remainder of their unhappy existence at the expense of the rate-payers, as pointed out by Dr. Clouston, who also wisely observed that “such a scheme would give the poor the same chance that the rich now had of securing recovery by the aid of the best possible advice.” The medical student of to-day in studying mental diseases principally meets with advanced or chronic cases, and seldom comes in contact with the disease in its early stages. Infirmary wards would therefore mitigate this serious disadvantage, besides providing him with material for a much wider scope. Legally speaking, such patients would not be looked upon as lunatics, though they were under the care of a “specialist.” The proposal has the unanimous support of the medical profession, and we have no doubt, if clearly placed before the general public in regard to its many benefits, their approval and support will appear in due course. The meeting unanimously agreed “to urge strongly on the managers of the Royal Infirmary to seriously consider the expediency of providing wards within, or in the immediate vicinity of, the institution for the treatment of incipient, transitory, and recent cases of insanity.” Sir John Batty Tuke in course of his remarks said: “If the managers did so, they would have the credit of being the first hospital authorities to take a wide, a broad, and a munificent view of the nature and treatment of insanity.” However, they have appointed a Committee to meet a deputation from the Society, and further developments will be interestingly and anxiously awaited, and it is to be hoped that an out-patient department will at least be established.

Notes on Current Topics.

Small-pox in London.

THE outbreak of small-pox continues to spread steadily in the metropolis. As might have been expected it has given rise to an immense flood of journalistic outpouring, chiefly from the anti-vaccinationist camp, in all parts of the United Kingdom. There is consolation, however, to be found in the fact that faddist theories are apt to crumble when

the small-pox comes, and men, women and children of all shades of Jennerian persuasion flock to the private or the public vaccinator. The district that has suffered most severely is Stepney, where the Rev. Harry Wilson, of St. Augustine's Church, has done great work as an apostle of vaccination. It appears that rumours were abroad in his parish that no less than seven women had lost their arms through having submitted to vaccination. He accordingly advertised offering a reward to anyone who would prove that any one had actually lost an arm from that cause. After three weeks the reward remained unclaimed. This most energetic and practical clergyman has also issued broadcast a leaflet from which the following paragraph deserves to be quoted in full:—“In the town of Gloucester there is a beautiful cemetery, and in one corner of the cemetery there are the graves of no less than 280 little children, all under ten years of age, all of whom died seven years ago, when a terrible attack of small-pox visited that town. Of these 280 children who died of small-pox, 279 were unvaccinated, and only one was vaccinated.” We venture to think that brief sermon deserves wide publication. There appears to be a good deal of method among the underwriters at Lloyd's who are granting insurances against small-pox. The original rate of 2s. 6d. per £100 for vaccinated, and 3s. 4d. for unvaccinated persons in non-infected areas has been raised to 5s. for non-vaccinated. In infected areas 10s., 20s., and even 30s. per £100 has been asked, while one or two districts are debarred altogether. Medical men and nurses are charged the exorbitant rate of 30s. per £100. The cost of the epidemic, directly and indirectly, will be very great. The chairman of the Hospital Committee of the Asylums Board last week announced that it would be necessary to increase the rates. The special extra expenditure for the half-year amounts to no less than £116,625. In the course of his annual statement he said that since August 10th last 4,468 small-pox patients had been admitted at South Wharf. That was as nearly as possible one case per 1,000 of the population. Nineteen persons died at the Wharf, and 4,449 had been sent on to the hospitals; 2,675 had been discharged recovered, and 739 had died. These figures, in the face of a steady weekly increase in cases, point to a sufficiently serious state of affairs. On Tuesday last week there were 70 fresh cases, and on Wednesday 56, on Thursday 69, on Friday 60, on Saturday 78, on Sunday 73, and on Monday 62. The total number of cases under treatment had mounted by midnight on Sunday to 1,530.

Army Medical Reform.

THE Secretary of War, Mr. Brodrick, has made an important declaration of policy in the Commons with regard to the future of the Army Medical Corps. He stated in so many words that the features of the scheme were increased pay, increased number of officers, additional opportunities for study, and a provision of special means of instruction if possible

in London. It is a thousand pities that the General Medical Council cannot give an authoritative opinion as to the vital changes involved in these proposals. From the point of view of many medical men, both in and out of the Service, the examination test of proficiency is simply fallacious and foredoomed to failure. Distinction is not won among civilians by passing examinations in the heyday of a professional career. Indeed, it is doubtful whether the system of high-standard examinations at the threshold of medical life is not on the whole a sterilising and delusive snare. So far as the Army scheme is concerned the weakest point in the whole thing is the fact that the Committee of distinguished medical men who advocated the changes in question, will, to a great extent, furnish the additional examiners and tutorial and professional staff that will be required. A further proposal of Mr. Brodrick's to attach officers to battalions is to be commended. It would be a valuable help at this juncture if the collective opinions of the rank and file of the Army Medical Service could be obtained with regard to the proposed examination test. As a rule, however, the officer is afraid to speak, although he would be a capital witness from first-hand knowledge of the inwardness of the situation.

"Tube" Railway Ventilation.

THE Central London Railway has at length taken steps to improve the ventilation of their "twopenny tube," as it is now named by assent of the populace. It had been shown that the percentage of carbonic acid between the stations was dangerously high, and the general assumption was that the impurity in question was derived from passengers. It seems not unlikely, however, that the gas may permeate the walls of the tube, in much the same way as carbonic acid gas collects in deep wells and mines. We have from time to time commented freely on the want of ventilation in this fresh departure in deep tunnel locomotion, because the prospect of its wide extension throughout the Kingdom is not altogether remote. It is gratifying to find that the Central London authorities are adopting some of our recommendations. Some months ago we pointed out that the air forced along one tube simply crossed through the doorways between the platforms and down the other tube. The air thus oscillated to and fro between the sections of the tunnel, and we suggested that the platform doorways should be closed. The plan adopted has been to place a powerful fan at Bond Street Station and close all the doorways, so that the tunnels can be swept of air through their whole length. The Company has not so far adopted our other suggestions as to the lifts, the state of which is still in some cases far from desirable. Thorough ventilation of the lifts at the surface could be most readily secured. The floor of the lifts should be of some impermeable material that could be swept instead of being washed, as the latter process converts the lift for an hour or two into a damp, steaming and noisome receptacle.

A Coroner on Winslow's Soothing Syrup.

MR. BRAXTON HICKS has the courage of his opinions when dealing with patent medicines. As coroner he has abundant opportunities of investigating the fatal results of administering many of the poisonous potions sold under the Government protection of a patent medicine label. In that respect he furnishes an example that might well be followed by other coroners, who in that way might do a vast deal both towards educating public opinion and towards securing fresh legislation. Not long ago he held an inquest upon the body of a baby, one year and seven months of age, to whom Mrs. Winslow's Soothing Syrup had been given. As most medical men know, or should know, that compound contains morphia, which is a most deadly drug in the case of infants. It appears that Mr. Hicks some time ago had an analysis made of the "syrup," and when it was proved to contain morphia the proprietors were compelled thereafter to put a poison label on the bottle. That has been done, however, in such small letters that it would as a rule be overlooked, as had been done by the mother of the baby which was the subject of the inquest under notice. The jury returned a verdict of death from natural causes, but we venture to hope the police will carry matters a step further. The rider of the verdict to the effect that medicines containing poison should be marked in red ink is good as far as it goes, but a better step would be to prohibit the sale of such pernicious stuff. If the General Medical Council were in any sense the guardian of the public health they would make strong representations to Government to abolish the present patent medicine system altogether.

The Etiology of Prostatic Hypertrophy.

It is really somewhat remarkable that so little should be known of the cause and pathological nature of the prostatic hypertrophy which embitters the declining years of so many elderly men. To call it an "idioplastic tumour," as did Sir Henry Thompson, does not help us greatly to understand its causation, especially as the tendency of age is in the direction of atrophy rather than hypertrophy so far as the genital organs are concerned. More plausible is the view promulgated by Reginald Harrison, viz., that the hypertrophy is due to over-exertion of this particular organ, being akin to the cardiac hypertrophy resulting from prolonged strain. This view, however plausible, is not absolutely in accordance with clinical experience which favours the view that over-exertion, that is to say chronic cystitis or venereal excesses, though it exaggerates any pre-existing condition, does not *per se* lead to hypertrophy, in the absence of some other ill-defined factor. On the whole it seems more reasonable to regard the overgrowth as analogous to fibro-myoma of the uterus. This view concords better with the erratic occurrence of this morbid development, and makes it essentially a constitutional condition rather than an accidental or acquired

infirmity. After all, however, the most plausible explanation is but a mere hypothesis, only a little more respectable than those speculations which bring diet, occupation, modes of living, abstinence and indulgence, sexual habits, gout, rheumatism and gonorrhœa into direct or indirect etiological relationship with the disease. As is almost invariably the case when the etiology has not been cleared up, the pathology of the disease is also incomplete. Our ignorance of these fundamental facts concerning prostatic hypertrophy has fortunately not deterred surgeons from working at the problem of its relief, with more or less success; but in a condition the consequences whereof are essentially of a purely mechanical nature the relief under the circumstances can only be partial and incomplete, hence the importance of studying the means of preventing its occurrence.

Touting by Public Vaccinators.

OUR contemporary, *Public Health*, discusses in a temperate article the position of the public vaccinator whose name, address, and qualifications are obtruded on the attention of persons who are in a position to pay for such services. The view is advanced that vaccination and revaccination are sanitary precautions, akin to the provision of isolation hospital accommodation, which ought properly to be chargeable to the local authority irrespective of social conditions, and in the abstract this view has much to recommend it. Since this indiscriminate publicity is certain to cause dissatisfaction, in that it amounts to deliberate touting for patients, it is suggested that the very real grievance thus inflicted on the general practitioner might be overcome by making every practitioner a public vaccinator in his own district (why his own district only?), he being supplied with vaccine lymph from the Government stations or with lymph under Government guarantee. In this way, it is urged, the entire profession would be interested in securing efficient multiple vaccination, and not that apology for vaccination which now unfortunately passes muster among a certain class of practitioners.

Medical Council Autocrats.
